

US009163284B2

(12) **United States Patent**
Liu et al.

(10) **Patent No.:** **US 9,163,284 B2**
(45) **Date of Patent:** **Oct. 20, 2015**

(54) **METHODS FOR IDENTIFYING A TARGET SITE OF A CAS9 NUCLEASE**

(71) Applicant: **President and Fellows of Harvard College, Cambridge, MA (US)**

(72) Inventors: **David R. Liu, Lexington, MA (US); Vikram Pattanayak, Cambridge, MA (US)**

(73) Assignee: **President and Fellows of Harvard College, Cambridge, MA (US)**

(*) Notice: Subject to any disclaimer, the term of this patent is extended or adjusted under 35 U.S.C. 154(b) by 0 days.

(21) Appl. No.: **14/320,370**

(22) Filed: **Jun. 30, 2014**

(65) **Prior Publication Data**

US 2015/0044191 A1 Feb. 12, 2015

(57) **ABSTRACT**

Some aspects of this disclosure provide strategies, methods, and reagents for determining nuclease target site preferences and specificity of site-specific endonucleases. Some methods provided herein utilize a novel “one-cut” strategy for screening a library of concatemers comprising repeat units of candidate nuclease target sites and constant insert regions to identify library members that can be cut by a nuclease of interest via sequencing of an intact target site adjacent and identical to a cut target site.

METHODS FOR IDENTIFYING A TARGET SITE OF A CAS9 NUCLEASE

RELATED APPLICATION

This application claims priority under 35 U.S.C. §119(e) to U.S. provisional patent application, U.S. Ser. No. 61/864,289, filed Aug. 9, 2013, the entire contents of which are incorporated herein by reference.

GOVERNMENT SUPPORT

This invention was made with U.S. Government support under grant numbers HR0011-11-2-0003 and N66001-12-C-4207, awarded by the Defense Advanced Research Projects Agency. The U.S. Government has certain rights in the invention.

BACKGROUND OF THE INVENTION

Site-specific endonucleases theoretically allow for the targeted manipulation of a single site within a genome and are useful in the context of gene targeting as well as for therapeutic applications. In a variety of organisms, including mammals, site-specific endonucleases have been used for genome engineering by stimulating either non-homologous end joining or homologous recombination. In addition to providing powerful research tools, site-specific nucleases also have potential as gene therapy agents, and two site-specific endonucleases have recently entered clinical trials: one, CCR5-2246, targeting a human CCR-5 allele as part of an anti-HIV therapeutic approach (NCT00842634, NCT01044654, NCT01252641), and the other one, VF24684, targeting the human VEGF-A promoter as part of an anti-cancer therapeutic approach (NCT01082926).

Specific cleavage of the intended nuclease target site without or with only minimal off-target activity is a prerequisite for clinical applications of site-specific endonuclease, and also for high-efficiency genomic manipulations in basic research applications, as imperfect specificity of engineered site-specific binding domains has been linked to cellular toxicity and undesired alterations of genomic loci other than the intended target. Most nucleases available today, however, exhibit significant off-target activity, and thus may not be suitable for clinical applications. Technology for evaluating nuclease specificity and for engineering nucleases with improved specificity are therefore needed.

SUMMARY OF THE INVENTION

Some aspects of this disclosure are based on the recognition that the reported toxicity of some engineered site-specific endonucleases is based on off-target DNA cleavage, rather than on off-target binding alone. Some aspects of this disclosure provide strategies, compositions, systems, and methods to evaluate and characterize the sequence specificity of site-specific nucleases, for example, RNA-programmable endonucleases, such as Cas9 endonucleases, zinc finger nucleases (ZNFs), homing endonucleases, or transcriptional activator-like element nucleases (TALENs).

The strategies, methods, and reagents of the present disclosure represent, in some aspects, an improvement over previous methods for assaying nuclease specificity. For example, some previously reported methods for determining nuclease target site specificity profiles by screening libraries of nucleic acid molecules comprising candidate target sites relied on a “two-cut” in vitro selection method which requires indirect

2

reconstruction of target sites from sequences of two half-sites resulting from two adjacent cuts of the nuclease of a library member nucleic acid (see e.g., PCT Application WO 2013/066438; and Pattanayak, V., Ramirez, C. L., Joung, J. K. & Liu, D. R. Revealing off-target cleavage specificities of zinc-finger nucleases by in vitro selection. *Nature methods* 8, 765-770 (2011), the entire contents of each of which are incorporated herein by reference). In contrast to such “two-cut” strategies, the methods of the present disclosure utilize an optimized “one cut” screening strategy, which allows for the identification of library members that have been cut at least once by the nuclease. As explained in more detail elsewhere herein, the “one-cut” selection strategies provided herein are compatible with single end high-throughput sequencing methods and do not require computational reconstruction of cleaved target sites from cut half-sites, thus streamlining the nuclease profiling process.

Some aspects of this disclosure provide in vitro selection methods for evaluating the cleavage specificity of endonucleases and for selecting nucleases with a desired level of specificity. Such methods are useful, for example, for characterizing an endonuclease of interest and for identifying a nuclease exhibiting a desired level of specificity, for example, for identifying a highly specific endonuclease for clinical applications.

Some aspects of this disclosure provide methods of identifying suitable nuclease target sites that are sufficiently different from any other site within a genome to achieve specific cleavage by a given nuclease without any or at least minimal off-target cleavage. Such methods are useful for identifying candidate nuclease target sites that can be cleaved with high specificity on a genomic background, for example, when choosing a target site for genomic manipulation in vitro or in vivo.

Some aspects of this disclosure provide methods of evaluating, selecting, and/or designing site-specific nucleases with enhanced specificity as compared to current nucleases. For example, provided herein are methods that are useful for selecting and/or designing site-specific nucleases with minimal off-target cleavage activity, for example, by designing variant nucleases with binding domains having decreased binding affinity, by lowering the final concentration of the nuclease, by choosing target sites that differ by at least three base pairs from their closest sequence relatives in the genome, and, in the case of RNA-programmable nucleases, by selecting a guide RNA that results in the fewest off-target sites being bound and/or cut.

Compositions and kits useful in the practice of the methods described herein are also provided.

Some aspects of this disclosure provide methods for identifying a target site of a nuclease. In some embodiments, the method comprises (a) providing a nuclease that cuts a double-stranded nucleic acid target site, wherein cutting of the target site results in cut nucleic acid strands comprising a 5' phosphate moiety; (b) contacting the nuclease of (a) with a library of candidate nucleic acid molecules, wherein each nucleic acid molecule comprises a concatemer of a sequence comprising a candidate nuclease target site and a constant insert sequence, under conditions suitable for the nuclease to cut a candidate nucleic acid molecule comprising a target site of the nuclease; and (c) identifying nuclease target sites cut by the nuclease in (b) by determining the sequence of an uncut nuclease target site on the nucleic acid strand that was cut by the nuclease in step (b). In some embodiments, the nuclease creates blunt ends. In some embodiments, the nuclease creates a 5' overhang. In some embodiments, the determining of step (c) comprises ligating a first nucleic acid adapter to the 5'

end of a nucleic acid strand that was cut by the nuclease in step (b) via 5'-phosphate-dependent ligation. In some embodiments, the nucleic acid adapter is provided in double-stranded form. In some embodiments, the 5'-phosphate-dependent ligation is a blunt end ligation. In some embodiments, the method comprises filling in the 5'-overhang before ligating the first nucleic acid adapter to the nucleic acid strand that was cut by the nuclease. In some embodiments, the determining of step (c) further comprises amplifying a fragment of the concatemer cut by the nuclease that comprises an uncut target site via a PCR reaction using a PCR primer that hybridizes with the adapter and a PCR primer that hybridizes with the constant insert sequence. In some embodiments, the method further comprises enriching the amplified nucleic acid molecules for molecules comprising a single uncut target sequence. In some embodiments, the step of enriching comprises a size fractionation. In some embodiments, the determining of step (c) comprises sequencing the nucleic acid strand that was cut by the nuclease in step (b), or a copy thereof obtained via PCR. In some embodiments, the library of candidate nucleic acid molecules comprises at least 10^8 , at least 10^9 , at least 10^{10} , at least 10^{11} , or at least 10^{12} different candidate nuclease cleavage sites. In some embodiments, the nuclease is a therapeutic nuclease which cuts a specific nuclease target site in a gene associated with a disease. In some embodiments, the method further comprises determining a maximum concentration of the therapeutic nuclease at which the therapeutic nuclease cuts the specific nuclease target site, and does not cut more than 10, more than 5, more than 4, more than 3, more than 2, more than 1, or no additional nuclease target sites. In some embodiments, the method further comprises administering the therapeutic nuclease to a subject in an amount effective to generate a final concentration equal or lower than the maximum concentration. In some embodiments, the nuclease is an RNA-programmable nuclease that forms a complex with an RNA molecule, and wherein the nuclease:RNA complex specifically binds a nucleic acid sequence complementary to the sequence of the RNA molecule. In some embodiments, the RNA molecule is a single-guide RNA (sgRNA). In some embodiments, the sgRNA comprises 5-50 nucleotides, 10-30 nucleotides, 15-25 nucleotides, 18-22 nucleotides, 19-21 nucleotides, e.g., 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, or 30 nucleotides. In some embodiments, the nuclease is a Cas9 nuclease. In some embodiments, the nuclease target site comprises a [sgRNA-complementary sequence]-[protospacer adjacent motif (PAM)] structure, and the nuclease cuts the target site within the sgRNA-complementary sequence. In some embodiments, the sgRNA-complementary sequence comprises 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, or 30 nucleotides. In some embodiments, the nuclease comprises an unspecific nucleic acid cleavage domain. In some embodiments, the nuclease comprises a FokI cleavage domain. In some embodiments, the nuclease comprises a nucleic acid cleavage domain that cleaves a target sequence upon cleavage domain dimerization. In some embodiments, the nuclease comprises a binding domain that specifically binds a nucleic acid sequence. In some embodiments, the binding domain comprises a zinc finger. In some embodiments, the binding domain comprises at least 2, at least 3, at least 4, or at least 5 zinc fingers. In some embodiments, the nuclease is a Zinc Finger Nuclease. In some embodiments, the binding domain comprises a Transcriptional Activator-Like Element. In some embodiments, the nuclease is a Transcriptional Activator-Like Element Nuclease (TALEN). In some embodiments, the nuclease is an organic compound. In some embodiments, the

nuclease comprises an enediyne functional group. In some embodiments, the nuclease is an antibiotic. In some embodiments, the compound is dynemicin, neocarzinostatin, calicheamicin, esperamicin, bleomycin, or a derivative thereof. In some embodiments, the nuclease is a homing endonuclease.

Some aspects of this disclosure provide libraries of nucleic acid molecules, in which each nucleic acid molecule comprises a concatemer of a sequence comprising a candidate nuclease target site and a constant insert sequence of 10-100 nucleotides. In some embodiments, the constant insert sequence is at least 15, at least 20, at least 25, at least 30, at least 35, at least 40, at least 45, at least 50, at least 55, at least 60, at least 65, at least 70, at least 75, at least 80, or at least 95 nucleotides long. In some embodiments, the constant insert sequence is not more than 15, not more than 20, not more than 25, not more than 30, not more than 35, not more than 40, not more than 45, not more than 50, not more than 55, not more than 60, not more than 65, not more than 70, not more than 75, not more than 80, or not more than 95 nucleotides long. In some embodiments, the candidate nuclease target sites are sites that can be cleaved by an RNA-programmable nuclease, a Zinc Finger Nuclease (ZFN), a Transcription Activator-Like Effector Nuclease (TALEN), a homing endonuclease, an organic compound nuclease, or an enediyne antibiotic (e.g., dynemicin, neocarzinostatin, calicheamicin, esperamicin, bleomycin). In some embodiments, the candidate nuclease target site can be cleaved by a Cas9 nuclease. In some embodiments, the library comprises at least 10^5 , at least 10^6 , at least 10^7 , at least 10^8 , at least 10^9 , at least 10^{10} , at least 10^{11} , or at least 10^{12} different candidate nuclease target sites. In some embodiments, the library comprises nucleic acid molecules of a molecular weight of at least 0.5 kDa, at least 1 kDa, at least 2 kDa, at least 3 kDa, at least 4 kDa, at least 5 kDa, at least 6 kDa, at least 7 kDa, at least 8 kDa, at least 9 kDa, at least 10 kDa, at least 12 kDa, or at least 15 kDa. In some embodiments, the library comprises candidate nuclease target sites that are variations of a known target site of a nuclease of interest. In some embodiments, the variations of a known nuclease target site comprise 10 or fewer, 9 or fewer, 8 or fewer, 7 or fewer, 6 or fewer, 5 or fewer, 4 or fewer, 3 or fewer, or 2 or fewer mutations as compared to a known nuclease target site. In some embodiments, the variations differ from the known target site of the nuclease of interest by more than 5%, more than 10%, more than 15%, more than 20%, more than 25%, or more than 30% on average, distributed binomially. In some embodiments, the variations differ from the known target site by no more than 10%, no more than 15%, no more than 20%, no more than 25%, nor more than 30%, no more than 40%, or no more than 50% on average, distributed binomially. In some embodiments, the nuclease of interest is a Cas9 nuclease, a zinc finger nuclease, a TALEN, a homing endonuclease, an organic compound nuclease, or an enediyne antibiotic (e.g., dynemicin, neocarzinostatin, calicheamicin, esperamicin, bleomycin). In some embodiments, the candidate nuclease target sites are Cas9 nuclease target sites that comprise a [sgRNA-complementary sequence]-[PAM] structure, wherein the sgRNA-complementary sequence comprises 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, or 30 nucleotides.

Some aspects of this disclosure provide methods for selecting a nuclease that specifically cuts a consensus target site from a plurality of nucleases. In some embodiments, the method comprises (a) providing a plurality of candidate nucleases that cut the same consensus sequence; (b) for each of the candidate nucleases of step (a), identifying a nuclease target site cleaved by the candidate nuclease that differ from

the consensus target site using a method provided herein; (c) selecting a nuclease based on the nuclease target site(s) identified in step (b). In some embodiments, the nuclease selected in step (c) is the nuclease that cleaves the consensus target site with the highest specificity. In some embodiments, the nuclease that cleaves the consensus target site with the highest specificity is the candidate nuclease that cleaves the lowest number of target sites that differ from the consensus site. In some embodiments, the candidate nuclease that cleaves the lowest number of target sites that are different from the consensus site in the context of a target genome. In some embodiments, the candidate nuclease selected in step (c) is a nuclease that does not cleave any target site other than the consensus target site. In some embodiments, the candidate nuclease selected in step (c) is a nuclease that does not cleave any target site other than the consensus target site within the genome of a subject at a therapeutically effective concentration of the nuclease. In some embodiments, the method further comprises contacting a genome with the nuclease selected in step (c). In some embodiments, the genome is a vertebrate, mammalian, human, non-human primate, rodent, mouse, rat, hamster, goat, sheep, cattle, dog, cat, reptile, amphibian, fish, nematode, insect, or fly genome. In some embodiments, the genome is within a living cell. In some embodiments, the genome is within a subject. In some embodiments, the consensus target site is within an allele that is associated with a disease or disorder. In some embodiments, cleavage of the consensus target site results in treatment or prevention of a disease or disorder, e.g., amelioration or prevention of at least one sign and/or symptom of the disease or disorder. In some embodiments, cleavage of the consensus target site results in the alleviation of a sign and/or symptom of the disease or disorder. In some embodiments, cleavage of the consensus target site results in the prevention of the disease or disorder. In some embodiments, the disease is HIV/AIDS. In some embodiments, the allele is a CCR5 allele. In some embodiments, the disease is a proliferative disease. In some embodiments, the disease is cancer. In some embodiments, the allele is a VEGFA allele.

Some aspects of this disclosure provide isolated nucleases that have been selected according to a method provided herein. In some embodiments, the nuclease has been engineered to cleave a target site within a genome. In some embodiments, the nuclease is a Cas9 nuclease comprising an sgRNA that is complementary to the target site within the genome. In some embodiments, the nuclease is a Zinc Finger Nuclease (ZFN) or a Transcription Activator-Like Effector Nuclease (TALEN), a homing endonuclease, or an organic compound nuclease (e.g., an enediyne, an antibiotic nuclease, dyncemicin, neocarzinostatin, calicheamicin, esperamicin, bleomycin, or a derivative thereof). In some embodiments, the nuclease has been selected based on cutting no other candidate target site, not more than one candidate target site, not more than two candidate target sites, not more than three candidate target sites, not more than four candidate target sites, not more than five candidate target sites, not more than six candidate target sites, not more than seven candidate target sites, not more than eight candidate target sites, not more than eight candidate target sites, not more than nine candidate target sites, or not more than ten candidate target sites in addition to its known nuclease target site.

Some aspects of this disclosure provide kits comprising a library of nucleic acid molecules comprising candidate nuclease target sites as provided herein. Some aspects of this disclosure provide kits comprising an isolated nuclease as provided herein. In some embodiments, the nuclease is a Cas9

nuclease. In some embodiments, the kit further comprises a nucleic acid molecule comprising a target site of the isolated nuclease. In some embodiments, the kit comprises an excipient and instructions for contacting the nuclease with the excipient to generate a composition suitable for contacting a nucleic acid with the nuclease. In some embodiments, the composition is suitable for contacting a nucleic acid within a genome. In some embodiments, the composition is suitable for contacting a nucleic acid within a cell. In some embodiments, the composition is suitable for contacting a nucleic acid within a subject. In some embodiments, the excipient is a pharmaceutically acceptable excipient.

Some aspects of this disclosure provide pharmaceutical compositions that are suitable for administration to a subject. In some embodiments, the composition comprises an isolated nuclease as provided herein. In some embodiments, the composition comprises a nucleic acid encoding such a nuclease. In some embodiments, the composition comprises a pharmaceutically acceptable excipient.

Other advantages, features, and uses of the invention will be apparent from the detailed description of certain non-limiting embodiments of the invention; the drawings, which are schematic and not intended to be drawn to scale; and the claims.

BRIEF DESCRIPTION OF THE DRAWINGS

FIGS. 1A-B. In vitro selection overview. (a) Cas9 complexed with a short guide RNA (sgRNA) recognizes ~20 bases of a target DNA substrate that is complementary to the sgRNA sequence and cleaves both DNA strands. The white triangles represent cleavage locations. (b) A modified version of our previously described in vitro selection was used to comprehensively profile Cas9 specificity. A concatemeric pre-selection DNA library in which each molecule contains one of 10^{12} distinct variants of a target DNA sequence (white rectangles) was generated from synthetic DNA oligonucleotides by ligation and rolling-circle amplification. This library was incubated with a Cas9:sgRNA complex of interest. Cleaved library members contain 5' phosphate groups (circles) and therefore are substrates for adapter ligation and PCR. The resulting amplicons were subjected to high-throughput DNA sequencing and computational analysis.

FIGS. 2A-H. In vitro selection results for Cas9:CLTA1 sgRNA. Heat maps²¹ show the specificity profiles of Cas9:CLTA1 sgRNA v2.1 under enzyme-limiting conditions (a, b), Cas9:CLTA1 sgRNA v1.0 under enzyme-saturating conditions (c, d), and Cas9:CLTA1 sgRNA v2.1 under enzyme-saturating conditions (e, f). Heat maps show all post-selection sequences (a, c, e) or only those sequences containing a single mutation in the 20-base pair sgRNA-specified target site and two-base pair PAM (b, d, f). Specificity scores of 1.0 and -1.0 corresponds to 100% enrichment for and against, respectively, a particular base pair at a particular position. Black boxes denote the intended target nucleotides. (g) Effect of Cas9:sgRNA concentration on specificity. Positional specificity changes between enzyme-limiting (200 nM DNA, 100 nM Cas9:sgRNA v2.1) and enzyme-saturating (200 nM DNA, 1000 nM Cas9:sgRNA v2.1) conditions, normalized to the maximum possible change in positional specificity, are shown for CLTA1. (h) Effect of sgRNA architecture on specificity. Positional specificity changes between sgRNA v1.0 and sgRNA v2.1 under enzyme-saturating conditions, normalized to the maximum possible change in positional specificity, are shown for CLTA1. See FIGS. 6-8, 25, and 26 for corresponding data for CLTA2, CLTA3, and CLTA4.

7

FIGS. 3A-D. Target sites profiled in this study. (A) The 5' end of the sgRNA has 20 nucleotides that are complementary to the target site. The target site contains an NGG motif (PAM) adjacent to the region of RNA:DNA complementarity. (B) Four human clathrin gene (CLTA) target sites are shown. Sequences correspond, from top to bottom, to SEQ ID NOs: 2-7, respectively. (C, D) Four human clathrin gene (CLTA) target sites are shown with sgRNAs. sgRNA v1.0 is shorter than sgRNA v2.1. The PAM is shown for each site. The non-PAM end of the target site corresponds to the 5' end of the sgRNA. Sequences in FIG. 3C correspond, from top to bottom, to SEQ ID NOs: 8-19, respectively. Sequences in FIG. 3D correspond, from top to bottom, to SEQ ID NOs: 20-31, respectively.

FIG. 4. Cas9:guide RNA cleavage of on-target DNA sequences in vitro. Discrete DNA cleavage assays on an approximately 1-kb linear substrate were performed with 200 nM on-target site and 100 nM Cas9:v1.0 sgRNA, 100 nM Cas9:v2.1 sgRNA, 1000 nM Cas9:v1.0 sgRNA, and 1000 nM Cas9:v2.1 sgRNA for each of four CLTA target sites. For CLTA1, CLTA2, and CLTA4, Cas9:v2.1 sgRNA shows higher activity than Cas9:v1.0 sgRNA. For CLTA3, the activities of the Cas9:v1.0 sgRNA and Cas9:v2.1 sgRNA were comparable.

FIGS. 5A-E. In vitro selection results for four target sites. In vitro selections were performed on 200 nM pre-selection library with 100 nM Cas9:sgRNA v2.1, 1000 nM Cas9:sgRNA v1.0, or 1000 nM Cas9:sgRNA v2.1. (A) Post-selection PCR products are shown for the 12 selections performed. DNA containing 1.5 repeats were quantified for each selection and pooled in equimolar amounts before gel purification and sequencing. (B-E) Distributions of mutations are shown for pre-selection (black) and post-selection libraries (colored). The post-selection libraries are enriched for sequences with fewer mutations than the pre-selection libraries. Mutations are counted from among the 20 base pairs specified by the sgRNA and the two-base pair PAM. P-values are <0.01 for all pairwise comparisons between distributions in each panel. P-values were calculated using t-tests, assuming unequal size and unequal variance.

FIGS. 6A-F. In vitro selection results for Cas9:CLTA2 sgRNA. Heat maps²⁴ show the specificity profiles of Cas9:CLTA2 sgRNA v2.1 under enzyme-limiting conditions (A, B), Cas9:CLTA2 sgRNA v1.0 under enzyme-excess conditions (C, D), and Cas9:CLTA2 sgRNA v2.1 under enzyme-excess conditions (E, F). Heat maps show all post-selection sequences (A, C, E) or only those sequences containing a single mutation in the 20-base pair sgRNA-specified target site and two-base pair PAM (B, D, F). Specificity scores of 1.0 and -1.0 corresponds to 100% enrichment for and against, respectively, a particular base pair at a particular position. Black boxes denote the intended target nucleotides.

FIGS. 7A-F. In vitro selection results for Cas9:CLTA3 sgRNA. Heat maps²⁴ show the specificity profiles of Cas9:CLTA3 sgRNA v2.1 under enzyme-limiting conditions (A, B), Cas9:CLTA3 sgRNA v1.0 under enzyme-excess conditions (C, D), and Cas9:CLTA3 sgRNA v2.1 under enzyme-saturating conditions (E, F). Heat maps show all post-selection sequences (A, C, E) or only those sequences containing a single mutation in the 20-base pair sgRNA-specified target site and two-base pair PAM (B, D, F). Specificity scores of 1.0 and -1.0 corresponds to 100% enrichment for and against, respectively, a particular base pair at a particular position. Black boxes denote the intended target nucleotides.

FIGS. 8A-F. In vitro selection results for Cas9:CLTA4 sgRNA. Heat maps²⁴ show the specificity profiles of Cas9:CLTA4 sgRNA v2.1 under enzyme-limiting conditions (A,

8

B), Cas9:CLTA4 sgRNA v1.0 under enzyme-excess conditions (C, D), and Cas9:CLTA4 sgRNA v2.1 under enzyme-saturating conditions (E, F). Heat maps show all post-selection sequences (A, C, E) or only those sequences containing a single mutation in the 20-base pair sgRNA-specified target site and two-base pair PAM (B, D, F). Specificity scores of 1.0 and -1.0 corresponds to 100% enrichment for and against, respectively, a particular base pair at a particular position. Black boxes denote the intended target nucleotides.

FIGS. 9A-D. In vitro selection results as sequence logos. Information content is plotted²⁵ for each target site position (1-20) specified by CLTA1 (A), CLTA2 (B), CLTA3 (C), and CLTA4 (D) sgRNA v2.1 under enzyme-limiting conditions. Positions in the PAM are labelled "P1," "P2," and "P3." Information content is plotted in bits. 2.0 bits indicates absolute specificity and 0 bits indicates no specificity.

FIGS. 10A-L. Tolerance of mutations distal to the PAM for CLTA1. The maximum specificity scores at each position are shown for the Cas9:CLTA1 v2.1 sgRNA selections when considering only those sequences with on-target base pairs in gray, while allowing mutations in the first 1-12 base pairs (a-l). The positions that are not constrained to on-target base pairs are indicated by dark bars. Higher specificity score values indicate higher specificity at a given position. The positions that were not allowed to contain any mutations (gray) were plotted with a specificity score of +1. For all panels, specificity scores were calculated from pre-selection library sequences and post-selection library sequences with an $n \geq 5,130$ and $n \geq 74,538$, respectively.

FIGS. 11A-L. Tolerance of mutations distal to the PAM for CLTA2. The maximum specificity scores at each position are shown for the Cas9:CLTA2 v2.1 sgRNA selections when considering only those sequences with on-target base pairs in gray, while allowing mutations in the first 1-12 base pairs (a-l). The positions that are not constrained to on-target base pairs are indicated by dark bars. Higher specificity score values indicate higher specificity at a given position. The positions that were not allowed to contain any mutations (gray) were plotted with a specificity score of +1. For all panels, specificity scores were calculated from pre-selection library sequences and post-selection library sequences with an $n \geq 3,190$ and $n \geq 25,365$, respectively.

FIGS. 12A-L. Tolerance of mutations distal to the PAM for CLTA3. The maximum specificity scores at each position are shown for the Cas9:CLTA3 v2.1 sgRNA selections when considering only those sequences with on-target base pairs in gray, while allowing mutations in the first 1-12 base pairs (a-l). The positions that are not constrained to on-target base pairs are indicated by dark bars. Higher specificity score values indicate higher specificity at a given position. The positions that were not allowed to contain any mutations (gray) were plotted with a specificity score of +1. For all panels, specificity scores were calculated from pre-selection library sequences and post-selection library sequences with an $n \geq 5,604$ and $n \geq 158,424$, respectively.

FIGS. 13A-I. Tolerance of mutations distal to the PAM for CLTA4. The maximum specificity scores at each position are shown for the Cas9:CLTA4 v2.1 sgRNA selections when considering only those sequences with on-target base pairs in gray, while allowing mutations in the first 1-12 base pairs (a-i). The positions that are not constrained to on-target base pairs are indicated by dark bars. Higher specificity score values indicate higher specificity at a given position. The positions that were not allowed to contain any mutations (gray) were plotted with a specificity score of +1. For all panels, specificity scores were calculated from pre-selection

library sequences and post-selection library sequences with an $n \geq 2,323$ and $n \geq 21,819$, respectively.

FIGS. 14A-L. Tolerance of mutations distal to the PAM in CLTA1 target sites. Distributions of mutations are shown for in vitro selection on 200 nM pre-selection library with 1000 nM Cas9:CLTA1 sgRNA v2.1. The number of mutations shown are in a 1-12 base pair target site subsequence farthest from the PAM (a-l) when the rest of the target site, including the PAM, contains only on-target base pairs. The pre-selection and post-selection distributions are similar for up to three base pairs, demonstrating tolerance for target sites with mutations in the three base pairs farthest from the PAM when the rest of the target sites have optimal interactions with the Cas9:sgRNA. For all panels, graphs were generated from pre-selection library sequences and post-selection library sequences with an $n \geq 5,130$ and $n \geq 74,538$, respectively.

FIGS. 15A-L. Tolerance of mutations distal to the PAM in CLTA2 target sites. Distributions of mutations are shown for in vitro selection on 200 nM pre-selection library with 1000 nM Cas9:CLTA2 sgRNA v2.1. The number of mutations shown are in a 1-12 base pair target site subsequence farthest from the PAM (a-l) when the rest of the target site, including the PAM, contains only on-target base pairs. The pre-selection and post-selection distributions are similar for up to three base pairs, demonstrating tolerance for target sites with mutations in the three base pairs farthest from the PAM when the rest of the target sites have optimal interactions with the Cas9:sgRNA. For all panels, graphs were generated from pre-selection library sequences and post-selection library sequences with an $n \geq 3,190$ and $n \geq 21,265$, respectively.

FIGS. 16A-L. Tolerance of mutations distal to PAM in CLTA3 target sites. Distributions of mutations are shown for in vitro selection on 200 nM pre-selection library with 1000 nM Cas9:CLTA3 sgRNA v2.1. The number of mutations shown are in a 1-12 base pair target site subsequence farthest from the PAM (a-l) when the rest of the target site, including the PAM, contains only on-target base pairs. The pre-selection and post-selection distributions are similar for up to three base pairs, demonstrating tolerance for target sites with mutations in the three base pairs farthest from the PAM when the rest of the target sites have optimal interactions with the Cas9:sgRNA. For all panels, graphs were generated from pre-selection library sequences and post-selection library sequences with an $n \geq 5,604$ and $n \geq 158,424$, respectively.

FIGS. 17A-L. Tolerance of mutations distal to PAM in CLTA4 target sites. Distributions of mutations are shown for in vitro selection on 200 nM pre-selection library with 1000 nM Cas9:CLTA4 sgRNA v2.1. The number of mutations shown are in a 1-12 base pair target site subsequence farthest from the PAM (a-l) when the rest of the target site, including the PAM, contains only on-target base pairs. The pre-selection and post-selection distributions are similar for up to three base pairs, demonstrating tolerance for target sites with mutations in the three base pairs farthest from the PAM when the rest of the target sites have optimal interactions with the Cas9:sgRNA. For all panels, graphs were generated from pre-selection library sequences and post-selection library sequences with an $n \geq 2,323$ and $n \geq 21,819$, respectively.

FIGS. 18A-D. Positional specificity patterns for 100 nM Cas9:sgRNA v2.1. Positional specificity, defined as the sum of the magnitude of the specificity score for each of the four possible base pairs recognized at a certain position in the target site, is plotted for each target site under enzyme-limiting conditions for sgRNA v2.1 (A-D). The positional specificity is shown as a value normalized to the maximum positional specificity value of the target site. Positional specificity is highest at the end of the target site proximal to the PAM and

is lowest in the middle of the target site and in the several nucleotides most distal to the PAM.

FIGS. 19A-D. Positional specificity patterns for 1000 nM Cas9:sgRNA v1.0. Positional specificity, defined as the sum of the magnitude of the specificity score for each of the four possible base pairs recognized at a certain position in the target site, is plotted for each target site under enzyme-excess conditions with sgRNA v1.0 (A-D). The positional specificity is shown as a value normalized to the maximum positional specificity value of the target site. Positional specificity is relatively constant across the target site but is lowest in the middle of the target site and in the several nucleotides most distal to the PAM.

FIGS. 20A-D. Positional specificity patterns for 1000 nM Cas9:sgRNA v2.1. Positional specificity, defined as the sum of the magnitude of the specificity score for each of the four possible base pairs recognized at a certain position in the target site, is plotted for each target site under enzyme-excess conditions with sgRNA v2.1 (A-D). The positional specificity is shown as a value normalized to the maximum positional specificity value of the target site. Positional specificity is relatively constant across the target site but is lowest in the middle of the target site and in the several nucleotides most distal to the PAM.

FIGS. 21A-D. PAM nucleotide preferences. The abundance in the pre-selection library and post-selection libraries under enzyme-limiting or enzyme-excess conditions are shown for all 16 possible PAM dinucleotides for selections with CLTA1 (a), CLTA2 (b), CLTA3 (c), and CLTA4 (d) sgRNA v2.1. GG dinucleotides increased in abundance in the post-selection libraries, while the other possible PAM dinucleotides decreased in abundance after the selection.

FIGS. 22A-D. PAM nucleotide preferences for on-target sites. Only post-selection library members containing no mutations in the 20 base pairs specified by the guide RNAs were included in this analysis. The abundance in the pre-selection library and post-selection libraries under enzyme-limiting and enzyme-excess conditions are shown for all 16 possible PAM dinucleotides for selections with CLTA1 (A), CLTA2 (B), CLTA3 (C), and CLTA4 (D) sgRNA v2.1. GG dinucleotides increased in abundance in the post-selection libraries, while the other possible PAM dinucleotides generally decreased in abundance after the selection, although this effect for the enzyme-excess concentrations of Cas9:sgRNA was modest or non-existent for many dinucleotides.

FIGS. 23A-D. PAM dinucleotide specificity scores. The specificity scores under enzyme-limiting and enzyme-excess conditions are shown for all 16 possible PAM dinucleotides (positions 2 and 3 of the three-nucleotide NGG PAM) for selections with CLTA1 (A), CLTA2 (B), CLTA3 (C), and CLTA4 (D) sgRNA v2.1. The specificity score indicates the enrichment of the PAM dinucleotide in the post-selection library relative to the pre-selection library, normalized to the maximum possible enrichment of that dinucleotide. A specificity score of +1.0 indicates that a dinucleotide is 100% enriched in the post-selection library, and a specificity score of -1.0 indicates that a dinucleotide is 100% de-enriched. GG dinucleotides were the most enriched in the post-selection libraries, and AG, GA, GC, GT, and TG show less relative de-enrichment compared to the other possible PAM dinucleotides.

FIGS. 24A-D. PAM dinucleotide specificity scores for on-target sites. Only post-selection library members containing no mutations in the 20 base pairs specified by the guide RNAs were included in this analysis. The specificity scores under enzyme-limiting and enzyme-excess conditions are shown for all 16 possible PAM dinucleotides (positions 2 and 3 of the

three-nucleotide NGG PAM) for selections with CLTA1 (A), CLTA2 (B), CLTA3 (C), and CLTA4 (D) sgRNA v2.1. The specificity score indicates the enrichment of the PAM dinucleotide in the post-selection library relative to the pre-selection library, normalized to the maximum possible enrichment of that dinucleotide. A specificity score of +1.0 indicates that a dinucleotide is 100% enriched in the post-selection library, and a specificity score of -1.0 indicates that a dinucleotide is 100% de-enriched. GG dinucleotides were the most enriched in the post-selection libraries, AG and GA nucleotides were neither enriched or de-enriched in at least one selection condition, and GC, GT, and TG show less relative de-enrichment compared to the other possible PAM dinucleotides.

FIGS. 25A-D. Effects of Cas9:sgRNA concentration on specificity. Positional specificity changes between enzyme-limiting (200 nM DNA, 100 nM Cas9:sgRNA v2.1) and enzyme-excess (200 nM DNA, 1000 nM Cas9:sgRNA v2.1) conditions are shown for selections with sgRNAs targeting CLTA1 (A), CLTA2 (B), CLTA3 (C), and CLTA4 (D) target sites. Lines indicate the maximum possible change in positional specificity for a given position. The highest changes in specificity occur proximal to the PAM as enzyme concentration is increased.

FIGS. 26A-D. Effects of sgRNA architecture on specificity. Positional specificity changes between Cas9:sgRNA v1.0 and Cas9:sgRNA v2.1 under enzyme-excess (200 nM DNA, 1000 nM Cas9:sgRNA v2.1) conditions are shown for selections with sgRNAs targeting CLTA1 (A), CLTA2 (B), CLTA3 (C), and CLTA4 (D) target sites. Lines indicate the maximum possible change in positional specificity for a given position.

FIG. 27. Cas9:guide RNA cleavage of off-target DNA sequences in vitro. Discrete DNA cleavage assays on a 96-bp linear substrate were performed with 200 nM DNA and 1000 nM Cas9:CLTA4 v2.1 sgRNA for the on-target CLTA4 site (CLTA4-0) and five CLTA4 off-target sites identified by in vitro selection. Enrichment values shown are from the in vitro selection with 1000 nM Cas9:CLTA4 v2.1 sgRNA. CLTA4-1 and CLTA4-3 were the most highly enriched sequences under these conditions. CLTA4-2a, CLTA4-2b, and CLTA4-2c are two-mutation sequences that represent a range of enrichment values from high enrichment to no enrichment to high de-enrichment. Lowercase letters indicate mutations relative to the on-target CLTA4 site. The enrichment values are qualitatively consistent with the observed amount of cleavage in vitro.

FIG. 28. Effect of guide RNA architecture and Cas9:sgRNA concentration on in vitro cleavage of an off-target site. Discrete DNA cleavage assays on a 96-bp linear substrate were performed with 200 nM DNA and 100 nM Cas9: v1.0 sgRNA, 100 nM Cas9:v2.1 sgRNA, 1000 nM Cas9:v1.0 sgRNA, or 1000 nM Cas9:v2.1 sgRNA for the CLTA4-3 off-target site (5' GggGATGTAGTGTTCACtGGG—mutations are shown in lowercase letters). DNA cleavage is observed under all four conditions tested, and cleavage rates are higher under enzyme-excess conditions, or with v2.1 sgRNA compared with v1.0 sgRNA.

DEFINITIONS

As used herein and in the claims, the singular forms “a,” “an,” and “the” include the singular and the plural reference unless the context clearly indicates otherwise. Thus, for example, a reference to “an agent” includes a single agent and a plurality of such agents.

The term “Cas9” or “Cas9 nuclease” refers to an RNA-guided nuclease comprising a Cas9 protein, or a fragment

thereof. A Cas9 nuclease is also referred to sometimes as a casn1 nuclease or a CRISPR (clustered regularly interspaced short palindromic repeat)-associated nuclease. CRISPR is an adaptive immune system that provides protection against mobile genetic elements (e.g., viruses, transposable elements and conjugative plasmids). CRISPR clusters contain spacers, sequences complementary to antecedent mobile elements, and target invading nucleic acids. CRISPR clusters are transcribed and processed into CRISPR RNA (crRNA). In type II CRISPR systems correct processing of pre-crRNA requires a trans-encoded small RNA (tracrRNA), endogenous ribonuclease 3 (mc) and a Cas9 protein. The tracrRNA serves as a guide for ribonuclease 3-aided processing of pre-crRNA. Subsequently, Cas9/crRNA/tracrRNA endonucleolytically cleaves linear or circular dsDNA target complementary to the spacer. The target strand not complementary to crRNA is first cut endonucleolytically, then trimmed 3'-5' exonucleolytically. In nature, DNA-binding and cleavage typically requires protein and both RNA species. However, single guide RNAs (“sgRNA”, or simply “gRNA”) can be engineered so as to incorporate aspects of both the crRNA and tracrRNA into a single RNA molecule. See, e.g., Jinek M., Chylinski K., Fonfara I., Hauer M., Doudna J. A., Charpentier E. *Science* 337: 816-821(2012), the entire contents of which is hereby incorporated by reference. Cas9 recognizes a short motif in the CRISPR repeat sequences (the PAM or protospacer adjacent motif) to help distinguish self versus non-self. Cas9 nuclease sequences and structures are well known to those of skill in the art (see, e.g., “Complete genome sequence of an M1 strain of *Streptococcus pyogenes*.” Ferretti J. J., McShan W. M., Ajdic D. J., Savic D. J., Savic G., Lyon K., Primeaux C., Sezate S., Suvorov A. N., Kenton S., Lai H. S., Lin S. P., Qian Y., Jia H. G., Najjar F. Z., Ren Q., Zhu H., Song L. expand/collapse author list McLaughlin R. E., *Proc. Natl. Acad. Sci. U.S.A.* 98:4658-4663(2001); “CRISPR RNA maturation by trans-encoded small RNA and host factor RNase III.” Deltcheva E., Chylinski K., Sharma C. M., Gonzales K., Chao Y., Pirzada Z. A., Eckert M. R., Vogel J., Charpentier E., *Nature* 471:602-607(2011); and “A programmable dual-RNA-guided DNA endonuclease in adaptive bacterial immunity.” Jinek M., Chylinski K., Fonfara I., Hauer M., Doudna J. A., Charpentier E. *Science* 337:816-821(2012), the entire contents of each of which are incorporated herein by reference). Cas9 orthologs have been described in various species, including, but not limited to, *S. pyogenes* and *S. thermophilus*. Additional suitable Cas9 nucleases and sequences will be apparent to those of skill in the art based on this disclosure, and such Cas9 nucleases and sequences include Cas9 sequences from the organisms and loci disclosed in Chylinski, Rhun, and Charpentier, “The tracrRNA and Cas9 families of type II CRISPR-Cas immunity systems” (2013) *RNA Biology* 10:5, 726-737; the entire contents of which are incorporated herein by reference. In some embodiments, proteins comprising Cas9 or fragments thereof proteins are referred to as “Cas9 variants.” A Cas9 variant shares homology to Cas9, or a fragment thereof. For example a Cas9 variant is at least about 70% identical, at least about 80% identical, at least about 90% identical, at least about 95% identical, at least about 98% identical, at least about 99% identical, at least about 99.5% identical, or at least about 99.9% to wild type Cas9. In some embodiments, the Cas9 variant comprises a fragment of Cas9 (e.g., a gRNA binding domain or a DNA-cleavage domain), such that the fragment is at least about 70% identical, at least about 80% identical, at least about 90% identical, at least about 95% identical, at least about 98% identical, at least about 99% identical, at least about 99.5% identical, or at least about 99.9% to the corresponding frag-

ment of wild type Cas9. In some embodiments, wild type Cas9 corresponds to Cas9 from *Streptococcus pyogenes* (NCBI Reference Sequence: NC_017053.1, SEQ ID NO:40 (nucleotide); SEQ ID NO:41 (amino acid)).

The term "concatemer," as used herein in the context of
35 nucleic acid molecules, refers to a nucleic acid molecule that
contains multiple copies of the same DNA sequences linked
in a series. For example, a concatemer comprising ten copies
of a specific sequence of nucleotides (e.g., [XYZ]₁₀), would
comprise ten copies of the same specific sequence linked to
40 each other in series, e.g., 5'-XYZXYZXYZXYZXYZ-
XYZXYZXYZXYZXYZ-3'. A concatemer may comprise any
number of copies of the repeat unit or sequence, e.g., at least
2 copies, at least 3 copies, at least 4 copies, at least 5 copies,
at least 10 copies, at least 100 copies, at least 1000 copies, etc.
45 An example of a concatemer of a nucleic acid sequence
comprising a nuclease target site and a constant insert
sequence would be [(target site)-(constant insert
sequence)]₃₀₀. A concatemer may be a linear nucleic acid
molecule, or may be circular.

The terms "conjugating," "conjugated," and "conjugation"
50 refer to an association of two entities, for example, of two
molecules such as two proteins, two domains (e.g., a binding
domain and a cleavage domain), or a protein and an agent,
e.g., a protein binding domain and a small molecule. In some
aspects, the association is between a protein (e.g., RNA-
programmable nuclease) and a nucleic acid (e.g., a guide
RNA). The association can be, for example, via a direct or
indirect (e.g., via a linker) covalent linkage or via non-cova-
55 lent interactions. In some embodiments, the association is
covalent. In some embodiments, two molecules are conju-
gated via a linker connecting both molecules. For example, in
some embodiments where two proteins are conjugated to
each other, e.g., a binding domain and a cleavage domain of
an engineered nuclease, to form a protein fusion, the two
65 proteins may be conjugated via a polypeptide linker, e.g., an
amino acid sequence connecting the C-terminus of one pro-
tein to the N-terminus of the other protein.

The term "consensus sequence," as used herein in the context of nucleic acid sequences, refers to a calculated sequence representing the most frequent nucleotide residues found at each position in a plurality of similar sequences. Typically, a consensus sequence is determined by sequence alignment in which similar sequences are compared to each other and similar sequence motifs are calculated. In the context of nuclease target site sequences, a consensus sequence of a nuclease target site may, in some embodiments, be the sequence most frequently bound, or bound with the highest affinity, by a given nuclease. With respect to RNA-programmable nuclease (e.g., Cas9) target site sequences, the consensus sequence may, in some embodiments, be the sequence or region to which a gRNA, or a plurality of gRNAs, is expected or designed to bind, e.g., based on complementary base pairing.

The term "effective amount," as used herein, refers to an amount of a biologically active agent that is sufficient to elicit a desired biological response. For example, in some embodiments, an effective amount of a nuclease may refer to the amount of the nuclease that is sufficient to induce cleavage of a target site specifically bound and cleaved by the nuclease. As will be appreciated by the skilled artisan, the effective amount of an agent, e.g., a nuclease, a hybrid protein, or a polynucleotide, may vary depending on various factors as, for example, on the desired biological response, the specific allele, genome, target site, cell, or tissue being targeted, and the agent being used.

The term "enediynes," as used herein, refers to a class of bacterial natural products characterized by either nine- and ten-membered rings containing two triple bonds separated by a double bond (see, e.g., K. C. Nicolaou; A. L. Smith; E. W. Yue (1993). "Chemistry and biology of natural and designed enediynes". PNAS 90 (13): 5881-5888; the entire contents of which are incorporated herein by reference). Some enediynes are capable of undergoing Bergman cyclization, and the resulting diradical, a 1,4-dehydrobenzene derivative, is capable of abstracting hydrogen atoms from the sugar backbone of DNA which results in DNA strand cleavage (see, e.g., S. Walker; R. Landovitz; W. D. Ding; G. A. Ellestad; D. Kahne (1992). "Cleavage behavior of calicheamicin gamma 1 and calicheamicin T". Proc Natl Acad Sci U.S.A. 89 (10): 4608-12; the entire contents of which are incorporated herein by reference). Their reactivity with DNA confers an antibiotic character to many enediynes, and some enediynes are clinically investigated as anticancer antibiotics. Nonlimiting examples of enediynes are dynemicin, neocarzinostatin, calicheamicin, esperamicin (see, e.g., Adrian L. Smith and K. C. Nicolaou, "The Enediyne Antibiotics" J. Med. Chem., 1996, 39 (11), pp 2103-2117; and Donald Borders, "Enediyne antibiotics as antitumor agents," Informa Healthcare; 1st edition (Nov. 23, 1994, ISBN-10: 0824789385; the entire contents of which are incorporated herein by reference).

The term "homing endonuclease," as used herein, refers to a type of restriction enzymes typically encoded by introns or inteins Edgell DR (February 2009). "Selfish DNA: homing endonucleases find a home". *Curr Biol* 19 (3): R115-R117; Jasin M (June 1996). "Genetic manipulation of genomes with rare-cutting endonucleases". *Trends Genet* 12 (6): 224-8; Burt A, Koufopanou V (December 2004). "Homing endonuclease genes: the rise and fall and rise again of a selfish element". *Curr Opin Genet Dev* 14 (6): 609-15; the entire contents of which are incorporated herein by reference. Homing endonuclease recognition sequences are long enough to occur randomly only with a very low probability (approximately once every 7×10^{10} bp), and are normally found in only one instance per genome.

The term "library," as used herein in the context of nucleic acids or proteins, refers to a population of two or more different nucleic acids or proteins, respectively. For example, a library of nuclease target sites comprises at least two nucleic acid molecules comprising different nuclease target sites. In some embodiments, a library comprises at least 10^1 , at least 10^2 , at least 10^3 , at least 10^4 , at least 10^5 , at least 10^6 , at least 10^7 , at least 10^8 , at least 10^9 , at least 10^{10} , at least 10^{11} , at least 10^{12} , at least 10^{13} , at least 10^{14} , or at least 10^{15} different nucleic acids or proteins. In some embodiments, the members of the library may comprise randomized sequences, for example, fully or partially randomized sequences. In some embodiments, the library comprises nucleic acid molecules that are unrelated to each other, e.g., nucleic acids comprising fully randomized sequences. In other embodiments, at least some members of the library may be related, for example, they may be variants or derivatives of a particular sequence, such as a consensus target site sequence.

The term "linker," as used herein, refers to a chemical group or a molecule linking two adjacent molecules or moieties, e.g., a binding domain and a cleavage domain of a nuclease. Typically, the linker is positioned between, or flanked by, two groups, molecules, or other moieties and connected to each one via a covalent bond, thus connecting the two. In some embodiments, the linker is an amino acid or a plurality of amino acids (e.g., a peptide or protein). In some embodiments, the linker is an organic molecule, group, polymer, or chemical moiety.

The term "nuclease," as used herein, refers to an agent, for example a protein or a small molecule, capable of cleaving a phosphodiester bond connecting nucleotide residues in a nucleic acid molecule. In some embodiments, a nuclease is a protein, e.g., an enzyme that can bind a nucleic acid molecule and cleave a phosphodiester bond connecting nucleotide residues within the nucleic acid molecule. A nuclease may be an endonuclease, cleaving a phosphodiester bonds within a polynucleotide chain, or an exonuclease, cleaving a phosphodiester bond at the end of the polynucleotide chain. In some embodiments, a nuclease is a site-specific nuclease, binding and/or cleaving a specific phosphodiester bond within a specific nucleotide sequence, which is also referred to herein as the "recognition sequence," the "nuclease target site," or the "target site." In some embodiments, a nuclease is a RNA-guided (i.e., RNA-programmable) nuclease, which complexes with (e.g., binds with) an RNA having a sequence that complements a target site, thereby providing the sequence specificity of the nuclease. In some embodiments, a nuclease recognizes a single stranded target site, while in other embodiments, a nuclease recognizes a double-stranded target site, for example a double-stranded DNA target site. The target sites of many naturally occurring nucleases, for example, many naturally occurring DNA restriction nucleases, are well known to those of skill in the art. In many cases, a DNA nuclease, such as EcoRI, HindIII, or BamHI, recognize a palindromic, double-stranded DNA target site of 4 to 10 base pairs in length, and cut each of the two DNA strands at a specific position within the target site. Some endonucleases cut a double-stranded nucleic acid target site symmetrically, i.e., cutting both strands at the same position so that the ends comprise base-paired nucleotides, also referred to herein as blunt ends. Other endonucleases cut a double-stranded nucleic acid target sites asymmetrically, i.e., cutting each strand at a different position so that the ends comprise unpaired nucleotides. Unpaired nucleotides at the end of a double-stranded DNA molecule are also referred to as "overhangs," e.g., as "5'-overhang" or as "3'-overhang," depending on whether the unpaired nucleotide(s) form(s) the

5' or the 3' end of the respective DNA strand. Double-stranded DNA molecule ends ending with unpaired nucleotide(s) are also referred to as sticky ends, as they can "stick to" other double-stranded DNA molecule ends comprising complementary unpaired nucleotide(s). A nuclease protein typically comprises a "binding domain" that mediates the interaction of the protein with the nucleic acid substrate, and also, in some cases, specifically binds to a target site, and a "cleavage domain" that catalyzes the cleavage of the phosphodiester bond within the nucleic acid backbone. In some embodiments a nuclease protein can bind and cleave a nucleic acid molecule in a monomeric form, while, in other embodiments, a nuclease protein has to dimerize or multimerize in order to cleave a target nucleic acid molecule. Binding domains and cleavage domains of naturally occurring nucleases, as well as modular binding domains and cleavage domains that can be fused to create nucleases binding specific target sites, are well known to those of skill in the art. For example, zinc fingers or transcriptional activator like elements can be used as binding domains to specifically bind a desired target site, and fused or conjugated to a cleavage domain, for example, the cleavage domain of FokI, to create an engineered nuclease cleaving the target site.

The terms "nucleic acid" and "nucleic acid molecule," as used herein, refer to a compound comprising a nucleobase and an acidic moiety, e.g., a nucleoside, a nucleotide, or a polymer of nucleotides. Typically, polymeric nucleic acids, e.g., nucleic acid molecules comprising three or more nucleotides are linear molecules, in which adjacent nucleotides are linked to each other via a phosphodiester linkage. In some embodiments, "nucleic acid" refers to individual nucleic acid residues (e.g. nucleotides and/or nucleosides). In some embodiments, "nucleic acid" refers to an oligonucleotide chain comprising three or more individual nucleotide residues. As used herein, the terms "oligonucleotide" and "polynucleotide" can be used interchangeably to refer to a polymer of nucleotides (e.g., a string of at least three nucleotides). In some embodiments, "nucleic acid" encompasses RNA as well as single and/or double-stranded DNA. Nucleic acids may be naturally occurring, for example, in the context of a genome, a transcript, an mRNA, tRNA, rRNA, siRNA, snRNA, a plasmid, cosmid, chromosome, chromatid, or other naturally occurring nucleic acid molecule. On the other hand, a nucleic acid molecule may be a non-naturally occurring molecule, e.g., a recombinant DNA or RNA, an artificial chromosome, an engineered genome, or fragment thereof, or a synthetic DNA, RNA, DNA/RNA hybrid, or including non-naturally occurring nucleotides or nucleosides. Furthermore, the terms "nucleic acid," "DNA," "RNA," and/or similar terms include nucleic acid analogs, i.e. analogs having other than a phosphodiester backbone. Nucleic acids can be purified from natural sources, produced using recombinant expression systems and optionally purified, chemically synthesized, etc. Where appropriate, e.g., in the case of chemically synthesized molecules, nucleic acids can comprise nucleoside analogs such as analogs having chemically modified bases or sugars, and backbone modifications. A nucleic acid sequence is presented in the 5' to 3' direction unless otherwise indicated. In some embodiments, a nucleic acid is or comprises natural nucleosides (e.g. adenosine, thymidine, guanosine, cytidine, uridine, deoxyadenosine, deoxythymidine, deoxyguanosine, and deoxycytidine); nucleoside analogs (e.g., 2-aminoadenosine, 2-thiothymidine, inosine, pyrrolo-pyrimidine, 3-methyl adenosine, 5-methylcytidine, 2-aminoadenosine, C5-bromouridine, C5-fluorouridine, C5-iodouridine, C5-propynyl-uridine, C5-propynyl-cytidine, C5-methylcytidine, 2-aminoadenosine, 7-deazaadenos-

ine, 7-deazaguanosine, 8-oxoadenosine, 8-oxoguanosine, O(6)-methylguanine, and 2-thiocytidine); chemically modified bases; biologically modified bases (e.g., methylated bases); intercalated bases; modified sugars (e.g., 2'-fluororibose, ribose, 2'-deoxyribose, arabinose, and hexose); and/or modified phosphate groups (e.g., phosphorothioates and 5'-N-phosphoramidite linkages).

The term "pharmaceutical composition," as used herein, refers to a composition that can be administered to a subject in the context of treatment of a disease or disorder. In some embodiments, a pharmaceutical composition comprises an active ingredient, e.g., a nuclease or a nucleic acid encoding a nuclease, and a pharmaceutically acceptable excipient.

The term "proliferative disease," as used herein, refers to any disease in which cell or tissue homeostasis is disturbed in that a cell or cell population exhibits an abnormally elevated proliferation rate. Proliferative diseases include hyperproliferative diseases, such as pre-neoplastic hyperplastic conditions and neoplastic diseases. Neoplastic diseases are characterized by an abnormal proliferation of cells and include both benign and malignant neoplasias. Malignant neoplasia is also referred to as cancer.

The terms "protein," "peptide," and "polypeptide" are used interchangeably herein, and refer to a polymer of amino acid residues linked together by peptide (amide) bonds. The terms refer to a protein, peptide, or polypeptide of any size, structure, or function. Typically, a protein, peptide, or polypeptide will be at least three amino acids long. A protein, peptide, or polypeptide may refer to an individual protein or a collection of proteins. One or more of the amino acids in a protein, peptide, or polypeptide may be modified, for example, by the addition of a chemical entity such as a carbohydrate group, a hydroxyl group, a phosphate group, a farnesyl group, an isofarnesyl group, a fatty acid group, a linker for conjugation, functionalization, or other modification, etc. A protein, peptide, or polypeptide may also be a single molecule or may be a multi-molecular complex. A protein, peptide, or polypeptide may be just a fragment of a naturally occurring protein or peptide. A protein, peptide, or polypeptide may be naturally occurring, recombinant, or synthetic, or any combination thereof. A protein may comprise different domains, for example, a nucleic acid binding domain and a nucleic acid cleavage domain. In some embodiments, a protein comprises a proteinaceous part, e.g., an amino acid sequence constituting a nucleic acid binding domain, and an organic compound, e.g., a compound that can act as a nucleic acid cleavage agent. In some embodiments, a protein is in a complex with, or in association with, a nucleic acid, e.g., RNA.

The term "randomized," as used herein in the context of nucleic acid sequences, refers to a sequence or residue within a sequence that has been synthesized to incorporate a mixture of free nucleotides, for example, a mixture of all four nucleotides A, T, G, and C. Randomized residues are typically represented by the letter N within a nucleotide sequence. In some embodiments, a randomized sequence or residue is fully randomized, in which case the randomized residues are synthesized by adding equal amounts of the nucleotides to be incorporated (e.g., 25% T, 25% A, 25% G, and 25% C) during the synthesis step of the respective sequence residue. In some embodiments, a randomized sequence or residue is partially randomized, in which case the randomized residues are synthesized by adding non-equal amounts of the nucleotides to be incorporated (e.g., 79% T, 7% A, 7% G, and 7% C) during the synthesis step of the respective sequence residue. Partial randomization allows for the generation of sequences that are templated on a given sequence, but have incorporated mutations at a desired frequency. For example, if a known nuclease

target site is used as a synthesis template, partial randomization in which at each step the nucleotide represented at the respective residue is added to the synthesis at 79%, and the other three nucleotides are added at 7% each, will result in a mixture of partially randomized target sites being synthesized, which still represent the consensus sequence of the original target site, but which differ from the original target site at each residue with a statistical frequency of 21% for each residue so synthesized (distributed binomially). In some embodiments, a partially randomized sequence differs from the consensus sequence by more than 5%, more than 10%, more than 15%, more than 20%, more than 25%, or more than 30% on average, distributed binomially. In some embodiments, a partially randomized sequence differs from the consensus site by no more than 10%, no more than 15%, no more than 20%, no more than 25%, nor more than 30%, no more than 40%, or no more than 50% on average, distributed binomially.

The term “RNA-programmable nuclease,” and “RNA-guided nuclease” are used interchangeably herein and refer to a nuclease that forms a complex with (e.g., binds or associates with) one or more RNA that is not a target for cleavage. In some embodiments, an RNA-programmable nuclease, when in a complex with an RNA, may be referred to as a nuclease:RNA complex. Typically, the bound RNA(s) is referred to as a guide RNA (gRNA) or a single-guide RNA (sgRNA). The gRNA/sgRNA comprises a nucleotide sequence that complements a target site, which mediates binding of the nuclease:RNA complex to said target site and providing the sequence specificity of the nuclease:RNA complex. In some embodiments, the RNA-programmable nuclease is the (CRISPR-associated system) Cas9 endonuclease, for example Cas9 (Csn1) from *Streptococcus pyogenes* (see, e.g., “Complete genome sequence of an M1 strain of *Streptococcus pyogenes*,” Ferretti J. J., McShan W. M., Ajdic D. J., Savic D. J., Savic G., Lyon K., Primeaux C., Sezate S., Suvorov A. N., Kenton S., Lai H. S., Lin S. P., Qian Y., Jia H. G., Najjar F. Z., Ren Q., Zhu H., Song L. expand/collapse author list McLaughlin R. E., Proc. Natl. Acad. Sci. U.S.A. 98:4658-4663(2001); “CRISPR RNA maturation by trans-encoded small RNA and host factor RNase III,” Deltcheva E., Chylinski K., Sharma C. M., Gonzales K., Chao Y., Pirzada Z. A., Eckert M. A., Charpentier E. Science 337:816-821(2012), the entire contents of each of which are incorporated herein by reference

Because RNA-programmable nucleases (e.g., Cas9) use RNA:DNA hybridization to determine target DNA cleavage sites, these proteins are able to cleave, in principle, any sequence specified by the guide RNA. Methods of using RNA-programmable nucleases, such as Cas9, for site-specific cleavage (e.g., to modify a genome) are known in the art (See e.g., Cong, L. et al. Multiplex genome engineering using CRISPR/Cas systems. *Science* 339, 819-823 (2013); Mali, P. et al. RNA-guided human genome engineering via Cas9. *Science* 339, 823-826 (2013); Hwang, W. Y. et al. Efficient genome editing in zebrafish using a CRISPR-Cas system. *Nature biotechnology* 31, 227-229 (2013); Jinek, M. et al. Genome engineering in *Saccharomyces cerevisiae* using CRISPR-Cas systems. *Nucleic acids research* (2013); Jiang, W. et al. RNA-guided editing of bacterial genomes using CRISPR-Cas systems. *Nature biotechnology* 31, 233-239 (2013); the entire contents of each of which are incorporated herein by reference).

The terms “small molecule” and “organic compound” are used interchangeably herein and refer to molecules, whether naturally-occurring or artificially created (e.g., via chemical synthesis) that have a relatively low molecular weight. Typically, an organic compound contains carbon. An organic compound may contain multiple carbon-carbon bonds, stereocenters, and other functional groups (e.g., amines, hydroxyl, carbonyls, or heterocyclic rings). In some embodiments, organic compounds are monomeric and have a molecular weight of less than about 1500 g/mol. In certain embodiments, the molecular weight of the small molecule is less than about 1000 g/mol or less than about 500 g/mol. In certain embodiments, the small molecule is a drug, for example, a drug that has already been deemed safe and effective for use in humans or animals by the appropriate governmental agency or regulatory body. In certain embodiments, the organic molecule is known to bind and/or cleave a nucleic acid. In some embodiments, the organic compound is an enediyne. In some embodiments, the organic compound is an antibiotic drug, for example, an anticancer antibiotic such as doxorubicin, neocarzinostatin, calicheamicin, esperamicin, bleomycin, or a derivative thereof.

The term “subject,” as used herein, refers to an individual organism, for example, an individual mammal. In some embodiments, the subject is a human. In some embodiments, the subject is a non-human mammal. In some embodiments, the subject is a non-human primate. In some embodiments, the subject is a rodent. In some embodiments, the subject is a sheep, a goat, a cattle, a cat, or a dog. In some embodiments, the subject is a vertebrate, an amphibian, a reptile, a fish, an insect, a fly, or a nematode.

The terms “target nucleic acid,” and “target genome,” as used herein in the context of nucleases, refer to a nucleic acid molecule or a genome, respectively, that comprises at least one target site of a given nuclease.

The term “target site,” used herein interchangeably with the term “nuclease target site,” refers to a sequence within a nucleic acid molecule that is bound and cleaved by a nuclease. A target site may be single-stranded or double-stranded. In the context of nucleases that dimerize, for example, nucleases comprising a FokI DNA cleavage domain, a target sites typically comprises a left-half site (bound by one monomer of the nuclease), a right-half site (bound by the second monomer of the nuclease), and a spacer sequence between the half sites in which the cut is made. This structure ([left-half site]-[spacer sequence]-[right-half site]) is referred to herein as an LSR structure. In some embodiments, the left-half site and/or the right-half site is between 10-18 nucleotides long. In some embodiments, either or both half-sites are shorter or longer. In some embodiments, the left and right half sites comprise different nucleic acid sequences. In the context of zinc finger nucleases, target sites may, in some embodiments comprise two half-sites that are each 6-18 bp long flanking a non-specified spacer region that is 4-8 bp long. In the context of TALENs, target sites may, in some embodiments, comprise two half-sites sites that are each 10-23 bp long flanking a non-specified spacer region that is 10-30 bp long. In the context of RNA-guided (e.g., RNA-programmable) nucleases, a target site typically comprises a nucleotide sequence that is complementary to the sgRNA of the RNA-programmable nuclease, and a protospacer adjacent motif (PAM) at the 3' end adjacent to the sgRNA-complementary sequence. For the RNA-guided nuclease Cas9, the target site may be, in some embodiments, 20 base pairs plus a 3 base pair PAM (e.g., NNN, wherein N represents any nucleotide). Typically, the first nucleotide of a PAM can be any nucleotide, while the two downstream nucleotides are specified depend-

ing on the specific RNA-guided nuclease. Exemplary target sites for RNA-guided nucleases, such as Cas9, are known to those of skill in the art and include, without limitation, NNG, NGN, NAG, and NGG, wherein N represents any nucleotide. In addition, Cas9 nucleases from different species (e.g., *S. thermophilus* instead of *S. pyogenes*) recognizes a PAM that comprises the sequence NGGNG. Additional PAM sequences are known, including, but not limited to NNA-GAAW and NAAR (see, e.g., Esvelt and Wang, Molecular Systems Biology, 9:641 (2013), the entire contents of which are incorporated herein by reference). For example, the target site of an RNA-guided nuclease, such as, e.g., Cas9, may comprise the structure [N_z]-[PAM], where each N is, independently, any nucleotide, and _z is an integer between 1 and 50. In some embodiments, _z is at least 2, at least 3, at least 4, at least 5, at least 6, at least 7, at least 8, at least 9, at least 10, at least 11, at least 12, at least 13, at least 14, at least 15, at least 16, at least 17, at least 18, at least 19, at least 20, at least 25, at least 30, at least 35, at least 40, at least 45, or at least 50. In some embodiments, _z is 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, or 50. In some embodiments, Z is 20.

The term “Transcriptional Activator-Like Effector,” (TALE) as used herein, refers to bacterial proteins comprising a DNA binding domain, which contains a highly conserved 33-34 amino acid sequence comprising a highly variable two-amino acid motif (Repeat Variable Di-residue, RVD). The RVD motif determines binding specificity to a nucleic acid sequence, and can be engineered according to methods well known to those of skill in the art to specifically bind a desired DNA sequence (see, e.g., Miller, Jeffrey; et. al. (February 2011). “A TALE nuclease architecture for efficient genome editing”. *Nature Biotechnology* 29 (2): 143-8; Zhang, Feng; et. al. (February 2011). “Efficient construction of sequence-specific TAL effectors for modulating mammalian transcription”. *Nature Biotechnology* 29 (2): 149-53; Geißler, R.; Scholze, H.; Hahn, S.; Streubel, J.; Bonas, U.; Behrens, S. E.; Boch, J. (2011), Shiu, Shin-Han. ed. “Transcriptional Activators of Human Genes with Programmable DNA-Specificity”. *PLoS ONE* 6 (5): e19509; Boch, Jens (February 2011). “TALEs of genome targeting”. *Nature Biotechnology* 29 (2): 135-6; Boch, Jens; et. al. (December 2009). “Breaking the Code of DNA Binding Specificity of TAL-Type III Effectors”. *Science* 326 (5959): 1509-12; and Moscou, Matthew J.; Adam J. Bogdanove (December 2009). “A Simple Cipher Governs DNA Recognition by TAL Effectors”. *Science* 326 (5959): 1501; the entire contents of each of which are incorporated herein by reference). The simple relationship between amino acid sequence and DNA recognition has allowed for the engineering of specific DNA binding domains by selecting a combination of repeat segments containing the appropriate RVDs.

The term “Transcriptional Activator-Like Element Nuclease,” (TALEN) as used herein, refers to an artificial nuclease comprising a transcriptional activator like effector DNA binding domain to a DNA cleavage domain, for example, a FokI domain. A number of modular assembly schemes for generating engineered TALE constructs have been reported (see e.g., Zhang, Feng; et. al. (February 2011). “Efficient construction of sequence-specific TAL effectors for modulating mammalian transcription”. *Nature Biotechnology* 29 (2): 149-53; Geißler, R.; Scholze, H.; Hahn, S.; Streubel, J.; Bonas, U.; Behrens, S. E.; Boch, J. (2011), Shiu, Shin-Han. ed. “Transcriptional Activators of Human Genes with Programmable DNA-Specificity”. *PLoS ONE* 6 (5): e19509; Cermak, T.; Doyle, E. L.; Christian, M.; Wang, L.;

Zhang, Y.; Schmidt, C.; Baller, J. A.; Somia, N. V. et al. (2011). “Efficient design and assembly of custom TALEN and other TAL effector-based constructs for DNA targeting”. *Nucleic Acids Research*; Morbitzer, R.; Elsaesser, J.; Hausner, J.; Lahaye, T. (2011). “Assembly of custom TALE-type DNA binding domains by modular cloning”. *Nucleic Acids Research*; Li, T.; Huang, S.; Zhao, X.; Wright, D. A.; Carpenter, S.; Spalding, M. H.; Weeks, D. P.; Yang, B. (2011). “Modularly assembled designer TAL effector nucleases for targeted gene knockout and gene replacement in eukaryotes”. *Nucleic Acids Research*; Weber, E.; Gruetzner, R.; Werner, S.; Engler, C.; Marillonnet, S. (2011). Bendahmane, Mohammed. ed. “Assembly of Designer TAL Effectors by Golden Gate Cloning”. *PLoS ONE* 6 (5): e19722; the entire contents of each of which are incorporated herein by reference.

The terms “treatment,” “treat,” and “treating,” refer to a clinical intervention aimed to reverse, alleviate, delay the onset of, or inhibit the progress of a disease or disorder, or one or more symptoms thereof, as described herein. As used herein, the terms “treatment,” “treat,” and “treating” refer to a clinical intervention aimed to reverse, alleviate, delay the onset of, or inhibit the progress of a disease or disorder, or one or more symptoms thereof, as described herein. In some embodiments, treatment may be administered after one or more symptoms have developed and/or after a disease has been diagnosed. In other embodiments, treatment may be administered in the absence of symptoms, e.g., to prevent or delay onset of a symptom or inhibit onset or progression of a disease. For example, treatment may be administered to a susceptible individual prior to the onset of symptoms (e.g., in light of a history of symptoms and/or in light of genetic or other susceptibility factors). Treatment may also be continued after symptoms have resolved, for example to prevent or delay their recurrence.

The term “zinc finger,” as used herein, refers to a small nucleic acid-binding protein structural motif characterized by a fold and the coordination of one or more zinc ions that stabilize the fold. Zinc fingers encompass a wide variety of differing protein structures (see, e.g., Klug A, Rhodes D (1987). “Zinc fingers: a novel protein fold for nucleic acid recognition”. Cold Spring Harb. Symp. Quant. Biol. 52: 473-82, the entire contents of which are incorporated herein by reference). Zinc fingers can be designed to bind a specific sequence of nucleotides, and zinc finger arrays comprising fusions of a series of zinc fingers, can be designed to bind virtually any desired target sequence. Such zinc finger arrays can form a binding domain of a protein, for example, of a nuclease, e.g., if conjugated to a nucleic acid cleavage domain. Different type of zinc finger motifs are known to those of skill in the art, including, but not limited to, Cys₂His₂, Gag knuckle, Treble clef, Zinc ribbon, Zn₂/Cys₆, and TAZ2 domain-like motifs (see, e.g., Krishna S S, Majumdar I, Grishin N V (January 2003). “Structural classification of zinc fingers: survey and summary”. *Nucleic Acids Res.* 31 (2): 532-50). Typically, a single zinc finger motif binds 3 or 4 nucleotides of a nucleic acid molecule. Accordingly, a zinc finger domain comprising 2 zinc finger motifs may bind 6-8 nucleotides, a zinc finger domain comprising 3 zinc finger motifs may bind 9-12 nucleotides, a zinc finger domain comprising 4 zinc finger motifs may bind 12-16 nucleotides, and so forth. Any suitable protein engineering technique can be employed to alter the DNA-binding specificity of zinc fingers and/or design novel zinc finger fusions to bind virtually any desired target sequence from 3-30 nucleotides in length (see, e.g., Pabo C O, Peisach E, Grant R A (2001). “Design and selection of novel cys2His2 Zinc finger proteins”. *Annual Review of Biochemistry* 70: 313-340; Jamieson A C, Miller J

C, Pabo C O (2003). "Drug discovery with engineered zinc-finger proteins". *Nature Reviews Drug Discovery* 2 (5): 361-368; and Liu Q, Segal D J, Ghiara J B, Barbas C F (May 1997). "Design of polydactyl zinc-finger proteins for unique addressing within complex genomes". *Proc. Natl. Acad. Sci. U.S.A.* 94 (11); the entire contents of each of which are incorporated herein by reference). Fusions between engineered zinc finger arrays and protein domains that cleave a nucleic acid can be used to generate a "zinc finger nuclease." A zinc finger nuclease typically comprises a zinc finger domain that binds a specific target site within a nucleic acid molecule, and a nucleic acid cleavage domain that cuts the nucleic acid molecule within or in proximity to the target site bound by the binding domain. Typical engineered zinc finger nucleases comprise a binding domain having between 3 and 6 individual zinc finger motifs and binding target sites ranging from 9 base pairs to 18 base pairs in length. Longer target sites are particularly attractive in situations where it is desired to bind and cleave a target site that is unique in a given genome.

The term "zinc finger nuclease," as used herein, refers to a nuclease comprising a nucleic acid cleavage domain conjugated to a binding domain that comprises a zinc finger array. In some embodiments, the cleavage domain is the cleavage domain of the type II restriction endonuclease FokI. Zinc finger nucleases can be designed to target virtually any desired sequence in a given nucleic acid molecule for cleavage, and the possibility to the design zinc finger binding domains to bind unique sites in the context of complex genomes allows for targeted cleavage of a single genomic site in living cells, for example, to achieve a targeted genomic alteration of therapeutic value. Targeting a double-strand break to a desired genomic locus can be used to introduce frame-shift mutations into the coding sequence of a gene due to the error-prone nature of the non-homologous DNA repair pathway. Zinc finger nucleases can be generated to target a site of interest by methods well known to those of skill in the art. For example, zinc finger binding domains with a desired specificity can be designed by combining individual zinc finger motifs of known specificity. The structure of the zinc finger protein Zif268 bound to DNA has informed much of the work in this field and the concept of obtaining zinc fingers for each of the 64 possible base pair triplets and then mixing and matching these modular zinc fingers to design proteins with any desired sequence specificity has been described (Pavletich N P, Pabo C O (May 1991). "Zinc finger-DNA recognition: crystal structure of a Zif268-DNA complex at 2.1 Å". *Science* 252 (5007): 809-17, the entire contents of which are incorporated herein). In some embodiments, separate zinc fingers that each recognize a 3 base pair DNA sequence are combined to generate 3-, 4-, 5-, or 6-finger arrays that recognize target sites ranging from 9 base pairs to 18 base pairs in length. In some embodiments, longer arrays are contemplated. In other embodiments, 2-finger modules recognizing 6-8 nucleotides are combined to generate 4-, 6-, or 8-zinc finger arrays. In some embodiments, bacterial or phage display is employed to develop a zinc finger domain that recognizes a desired nucleic acid sequence, for example, a desired nuclease target site of 3-30 bp in length. Zinc finger nucleases, in some embodiments, comprise a zinc finger binding domain and a cleavage domain fused or otherwise conjugated to each other via a linker, for example, a polypeptide linker. The length of the linker determines the distance of the cut from the nucleic acid sequence bound by the zinc finger domain. If a shorter linker is used, the cleavage domain will cut the nucleic acid closer to the bound nucleic acid sequence, while a longer linker will result in a greater distance between the cut and the bound nucleic acid sequence. In

some embodiments, the cleavage domain of a zinc finger nuclease has to dimerize in order to cut a bound nucleic acid. In some such embodiments, the dimer is a heterodimer of two monomers, each of which comprise a different zinc finger binding domain. For example, in some embodiments, the dimer may comprise one monomer comprising zinc finger domain A conjugated to a FokI cleavage domain, and one monomer comprising zinc finger domain B conjugated to a FokI cleavage domain. In this nonlimiting example, zinc finger domain A binds a nucleic acid sequence on one side of the target site, zinc finger domain B binds a nucleic acid sequence on the other side of the target site, and the dimerize FokI domain cuts the nucleic acid in between the zinc finger domain binding sites.

DETAILED DESCRIPTION OF CERTAIN EMBODIMENTS OF THE INVENTION

Introduction

Site-specific nucleases are powerful tools for targeted genome modification in vitro or in vivo. Some site specific nucleases can theoretically achieve a level of specificity for a target cleavage site that would allow one to target a single unique site in a genome for cleavage without affecting any other genomic site. It has been reported that nuclease cleavage in living cells triggers a DNA repair mechanism that frequently results in a modification of the cleaved, repaired genomic sequence, for example, via homologous recombination. Accordingly, the targeted cleavage of a specific unique sequence within a genome opens up new avenues for gene targeting and gene modification in living cells, including cells that are hard to manipulate with conventional gene targeting methods, such as many human somatic or embryonic stem cells. Nuclease-mediated modification of disease-related sequences, e.g., the CCR-5 allele in HIV/AIDS patients, or of genes necessary for tumor neovascularization, can be used in the clinical context, and two site specific nucleases are currently in clinical trials.

One important aspect in the field of site-specific nuclease-mediated modification are off-target nuclease effects, e.g., the cleavage of genomic sequences that differ from the intended target sequence by one or more nucleotides. Undesired side effects of off-target cleavage range from insertion into unwanted loci during a gene targeting event to severe complications in a clinical scenario. Off-target cleavage of sequences encoding essential gene functions or tumor suppressor genes by an endonuclease administered to a subject may result in disease or even death of the subject. Accordingly, it is desirable to characterize the cleavage preferences of a nuclease before using it in the laboratory or the clinic in order to determine its efficacy and safety. Further, the characterization of nuclease cleavage properties allows for the selection of the nuclease best suited for a specific task from a group of candidate nucleases, or for the selection of evolution products obtained from a plurality of nucleases. Such a characterization of nuclease cleavage properties may also inform the de-novo design of nucleases with enhanced properties, such as enhanced specificity or efficiency.

In many scenarios where a nuclease is employed for the targeted manipulation of a nucleic acid, cleavage specificity is a crucial feature. The imperfect specificity of some engineered nuclease binding domains can lead to off-target cleavage and undesired effects both in vitro and in vivo. Current methods of evaluating site-specific nuclease specificity, including ELISA assays, microarrays, one-hybrid systems, SELEX, and its variants, and Rosetta-based computational

25

predictions, are all premised on the assumption that the binding specificity of the nuclease is equivalent or proportionate to their cleavage specificity.

It was previously discovered that the prediction of nuclease off-target binding effects constitute an imperfect approximation of a nuclease's off-target cleavage effects that may result in undesired biological effects (see PCT Application WO 2013/066438; and Pattanayak, V., Ramirez, C. L., Joung, J. K. & Liu, D. R. Revealing off-target cleavage specificities of zinc-finger nucleases by in vitro selection. *Nature methods* 8, 765-770 (2011), the entire contents of each of which are incorporated herein by reference). This finding was consistent with the notion that the reported toxicity of some site specific DNA nucleases results from off-target DNA cleavage, rather than off-target binding alone.

The methods and reagents of the present disclosure represent, in some aspects, an improvement over previous methods and allow for an accurate evaluation of a given nuclease's target site specificity and provide strategies for the selection of suitable unique target sites and the design or selection of highly specific nucleases for the targeted cleavage of a single site in the context of a complex genome. For example, some previously reported methods for determining nuclease target site specificity profiles by screening libraries of nucleic acid molecules comprising candidate target sites relied on a "two-cut" in vitro selection method which requires indirect reconstruction of target sites from sequences of two half-sites resulting from two adjacent cuts of the nuclease of a library member nucleic acid (see e.g., Pattanayak, V. et al., *Nature Methods* 8, 765-770 (2011)). In contrast to such "two-cut" strategies, the methods of the present disclosure utilize a "one cut" screening strategy, which allows for the identification of library members that have been cut at least once by the nuclease. The "one-cut" selection strategies provided herein are compatible with single end high-throughput sequencing methods and do not require computational reconstruction of cleaved target sites from cut half-sites because they feature, in some embodiments, direct sequencing of an intact target nuclease sequence in a cut library member nucleic acid.

Additionally, the presently disclosed "one-cut" screening methods utilize concatemers of a candidate nuclease target site and constant insert region that are about 10-fold shorter than previously reported constructs used for two-cut strategies (~50 bp repeat sequence length versus ~500 bp repeat sequence length in previous reports). This difference in repeat sequence length in the concatemers of the library allows for the generation of highly complex libraries of candidate nuclease target sites, e.g., of libraries comprising 10^{12} different candidate nuclease target sequences. As described herein, an exemplary library of such complexity has been generated, templated on a known Cas9 nuclease target site by varying the sequence of the known target site. The exemplary library demonstrated that a greater than 10-fold coverage of all sequences with eight or fewer mutations of the known target site can be achieved using the strategies provided herein. The use of a shorter repeat sequence also allows the use of single-end sequencing, since both a cut half-site and an adjacent uncut site of the same library member are contained within a 100 nucleotide sequencing read.

The strategies, methods, libraries, and reagents provided herein can be utilized to analyze the sequence preferences and specificity of any site-specific nuclease, for example, to Zinc Finger Nucleases (ZFNs), Transcription Activator-Like Effector Nucleases (TALENs), homing endonucleases, organic compound nucleases, and enediyne antibiotics (e.g., dynemicin, neocarzinostatin, calicheamicin, esperamicin,

26

bleomycin). Suitable nucleases in addition to the ones described herein will be apparent to those of skill in the art based on this disclosure.

Further, the methods, reagents, and strategies provided herein allow those of skill in the art to identify, design, and/or select nucleases with enhanced specificity and minimize the off-target effects of any given nuclease (e.g., site-specific nucleases such as ZFNs, and TALENs which produce cleavage products with sticky ends, as well as RNA-programmable nucleases, for example Cas9, which produce cleavage products having blunt ends). While of particular relevance to DNA and DNA-cleaving nucleases, the inventive concepts, methods, strategies, and reagents provided herein are not limited in this respect, but can be applied to any nucleic acid:nuclease pair.

Identifying Nuclease Target Sites Cleaved by a Site-Specific Nuclease

Some aspects of this disclosure provide improved methods and reagents to determine the nucleic acid target sites cleaved by any site-specific nuclease. The methods provided herein can be used for the evaluation of target site preferences and specificity of both nucleases that create blunt ends and nucleases that create sticky ends. In general, such methods comprise contacting a given nuclease with a library of target sites under conditions suitable for the nuclease to bind and cut a target site, and determining which target sites the nuclease actually cuts. A determination of a nuclease's target site profile based on actual cutting has the advantage over methods that rely on binding in that it measures a parameter more relevant for mediating undesired off-target effects of site-specific nucleases. In general, the methods provided herein comprise ligating an adapter of a known sequence to nucleic acid molecules that have been cut by a nuclease of interest via 5'-phosphate-dependent ligation. Accordingly, the methods provided herein are particularly useful for identifying target sites cut by nucleases that leave a phosphate moiety at the 5'-end of the cut nucleic acid strand when cleaving their target site. After ligating an adapter to the 5'-end of a cut nucleic acid strand, the cut strand can directly be sequenced using the adapter as a sequencing linker, or a part of the cut library member concatemer comprising an intact target site identical to the cut target site can be amplified via PCR and the amplification product can then be sequenced.

In some embodiments, the method comprises (a) providing a nuclease that cuts a double-stranded nucleic acid target site, wherein cutting of the target site results in cut nucleic acid strands comprising a 5'-phosphate moiety; (b) contacting the nuclease of (a) with a library of candidate nucleic acid molecules, wherein each nucleic acid molecule comprises a concatemer of a sequence comprising a candidate nuclease target site and a constant insert sequence, under conditions suitable for the nuclease to cut a candidate nucleic acid molecule comprising a target site of the nuclease; and (c) identifying nuclease target sites cut by the nuclease in (b) by determining the sequence of an uncut nuclease target site on the nucleic acid strand that was cut by the nuclease in step (b).

In some embodiments, the method comprises providing a nuclease and contacting the nuclease with a library of candidate nucleic acid molecules comprising candidate target sites. In some embodiments, the candidate nucleic acid molecules are double-stranded nucleic acid molecules. In some embodiments, the candidate nucleic acid molecules are DNA molecules. In some embodiments, each nucleic acid molecule in the library comprises a concatemer of a sequence comprising a candidate nuclease target site and a constant insert sequence. For example, in some embodiments, the library comprises nucleic acid molecules that comprise the structure

27

R_1 -[(candidate nuclease target site)-(constant insert sequence)]_n- R_2 , wherein R_1 and R_2 are, independently, nucleic acid sequences that may comprise a fragment of the [(candidate nuclease target site)-(constant insert sequence)] structure, and n is an integer between 2 and y . In some embodiments, y is at least 10^1 , at least 10^2 , at least 10^3 , at least 10^4 , at least 10^5 , at least 10^6 , at least 10^7 , at least 10^8 , at least 10^9 , at least 10^{10} , at least 10^{11} , at least 10^{12} , at least 10^{13} , at least 10^{14} , or at least 10^{15} . In some embodiments, y is less than 10^2 , less than 10^3 , less than 10^4 , less than 10^5 , less than 10^6 , less than 10^7 , less than 10^8 , less than 10^9 , less than 10^{10} , less than 10^{11} , less than 10^{12} , less than 10^{13} , less than 10^{14} , or less than 10^{15} .

For example, in some embodiments, the candidate nucleic acid molecules of the library comprise a candidate nuclease target site of the structure [(N_Z)-(PAM)], and, thus, the nucleic acid molecules of the library comprise the structure R_1 -[(N_Z)-(PAM)-(constant region)]_X- R_2 , wherein R_1 and R_2 are, independently, nucleic acid sequences that may comprise a fragment of the [(N_Z)-(PAM)-(constant region)] repeat unit; each N represents, independently, any nucleotide; Z is an integer between 1 and 50; and X is an integer between 2 and y . In some embodiments, y is at least 10^1 , at least 10^2 , at least 10^3 , at least 10^4 , at least 10^5 , at least 10^6 , at least 10^7 , at least 10^8 , at least 10^9 , at least 10^{10} , at least 10^{11} , at least 10^{12} , at least 10^{13} , at least 10^{14} , or at least 10^{15} . In some embodiments, y is less than 10^2 , less than 10^3 , less than 10^4 , less than 10^5 , less than 10^6 , less than 10^7 , less than 10^8 , less than 10^9 , less than 10^{10} , less than 10^{11} , less than 10^{12} , less than 10^{13} , less than 10^{14} , or less than 10^{15} . In some embodiments, Z is at least 2, at least 3, at least 4, at least 5, at least 6, at least 7, at least 8, at least 9, at least 10, at least 11, at least 12, at least 13, at least 14, at least 15, at least 16, at least 17, at least 18, at least 19, at least 20, at least 25, at least 30, at least 35, at least 40, at least 45, or at least 50. In some embodiments, Z is 20. Each N represents, independently, any nucleotide. Accordingly, a sequence provided as N_Z with $Z=2$ would be NN, with each N , independently, representing A, T, G, or C. Accordingly, N_Z with $Z=2$ can represent AA, AT, AG, AC, TA, TT, TG, TC, GA, GT, GG, GC, CA, CT, CG, and CC.

In other embodiments, the candidate nucleic acid molecules of the library comprise a candidate nuclease target site of the structure [left-half site]-[spacer sequence]-[right-half site] ("LSR"), and, thus, the nucleic acid molecules of the library comprise the structure R_1 -[(LSR)-(constant region)]_X- R_2 , wherein R_1 and R_2 are, independently, nucleic acid sequences that may comprise a fragment of the [(LSR)-(constant region)] repeat unit, and X is an integer between 2 and y . In some embodiments, y is at least 10^1 , at least 10^2 , at least 10^3 , at least 10^4 , at least 10^5 , at least 10^6 , at least 10^7 , at least 10^8 , at least 10^9 , at least 10^{10} , at least 10^{11} , at least 10^{12} , at least 10^{13} , at least 10^{14} , or at least 10^{15} . In some embodiments, y is less than 10^2 , less than 10^3 , less than 10^4 , less than 10^5 , less than 10^6 , less than 10^7 , less than 10^8 , less than 10^9 , less than 10^{10} , less than 10^{11} , less than 10^{12} , less than 10^{13} , less than 10^{14} , or less than 10^{15} . The constant region, in some embodiments, is of a length that allows for efficient self-ligation of a single repeat unit. Suitable lengths will be apparent to those of skill in the art. For example, in some embodiments, the constant region is between 5 and 100 base pairs long, for example, about 5 base pairs, about 10 base pairs, about 15 base pairs, about 20 base pairs, about 25 base pairs, about 30 base pairs, about 35 base pairs, about 40 base pairs, about 50 base pairs, about 60 base pairs, about 70 base pairs, about 80 base pairs, about 90 base pairs, or about 100 base pairs long. In some embodiments, the constant region is 16 base pairs long. In some embodiments, the nuclease cuts a

28

double-stranded nucleic acid target site and creates blunt ends. In other embodiments, the nuclease creates a 5'-overhang. In some such embodiments, the target site comprises a [left-half site]-[spacer sequence]-[right-half site] (LSR) structure, and the nuclease cuts the target site within the spacer sequence.

In some embodiments, a nuclease cuts a double-stranded target site and creates blunt ends. In some embodiments, a nuclease cuts a double-stranded target site and creates an overhang, or sticky end, for example, a 5'-overhang. In some such embodiments, the method comprises filling in the 5'-overhangs of nucleic acid molecules produced from a nucleic acid molecule that has been cut once by the nuclease, wherein the nucleic acid molecules comprise a constant insert sequence flanked by a left or right half-site and cut spacer sequence on one side, and an uncut target site sequence on the other side, thereby creating blunt ends.

In some embodiments, the determining of step (c) comprises ligating a first nucleic acid adapter to the 5' end of a nucleic acid strand that was cut by the nuclease in step (b) via 5'-phosphate-dependent ligation. In some embodiments, the nuclease creates blunt ends. In such embodiments, an adapter can directly be ligated to the blunt ends resulting from the nuclease cut of the target site by contacting the cut library members with a double-stranded, blunt-ended adapter lacking 5' phosphorylation. In some embodiments, the nuclease creates an overhang (sticky end). In some such embodiments, an adapter may be ligated to the cut site by contacting the cut library member with an excess of adapter having a compatible sticky end. If a nuclease is used that cuts within a constant spacer sequence between variable half-sites, the sticky end can be designed to match the 5' overhang created from the spacer sequence. In embodiments, where the nuclease cuts within a variable sequence, a population of adapters having a variable overhang sequence and a constant annealed sequence (for use as a sequencing linker or PCR primer) may be used, or the 5' overhangs may be filled in to form blunt ends before adapter ligation.

In some embodiments, the determining of step (c) further comprises amplifying a fragment of the concatemer cut by the nuclease that comprises an uncut target site via PCR using a PCR primer that hybridizes with the adapter and a PCR primer that hybridizes with the constant insert sequence. Typically, the amplification of concatemers via PCR will yield amplicons comprising at least one intact candidate target site identical to the cut target sites because the target sites in each concatemer are identical. For single-direction sequencing, an enrichment of amplicons that comprise one intact target site, no more than two intact target sites, no more than three intact target sites, no more than four intact target sites, or no more than five intact target sites may be desirable. In embodiments where PCR is used for amplification of cut nucleic acid molecules, the PCR parameters can be optimized to favor the amplification of short sequences and disfavor the amplification of longer sequences, e.g., by using a short elongation time in the PCR cycle. Another possibility for enrichment of short amplicons is size fractionation, e.g., via gel electrophoresis or size exclusion chromatography. Size fractionation can be performed before and/or after amplification. Other suitable methods for enrichment of short amplicons will be apparent to those of skill in the art and the disclosure is not limited in this respect.

In some embodiments, the determining of step (c) comprises sequencing the nucleic acid strand that was cut by the nuclease in step (b), or a copy thereof obtained via amplifi-

cation, e.g., by PCR. Sequencing methods are well known to those of skill in the art. The disclosure is not limited in this respect.

In some embodiments, the nuclease being profiled using the inventive system is an RNA-programmable nuclease that forms a complex with an RNA molecule, and wherein the nuclease:RNA complex specifically binds a nucleic acid sequence complementary to the sequence of the RNA molecule. In some embodiments, the RNA molecule is a single-guide RNA (sgRNA). In some embodiments, the sgRNA comprises 5-50 nucleotides, 10-30 nucleotides, 15-25 nucleotides, 18-22 nucleotides, 19-21 nucleotides, e.g., 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, or 30 nucleotides. In some embodiments, the sgRNA comprises 5-50 nucleotides, 10-30 nucleotides, 15-25 nucleotides, 18-22 nucleotides, 19-21 nucleotides, e.g., 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, or 30 nucleotides that are complementary to a sequence of the nuclease target site. In some embodiments, the sgRNA comprises 20 nucleotides that are complementary to the nuclease target site. In some embodiments, the nuclease is a Cas9 nuclease. In some embodiments, the nuclease target site comprises a [sgRNA-complementary sequence]-[protospacer adjacent motif (PAM)] structure, and the nuclease cuts the target site within the sgRNA-complementary sequence. In some embodiments, the sgRNA-complementary sequence comprises 5-50 nucleotides, 10-30 nucleotides, 15-25 nucleotides, 18-22 nucleotides, 19-21 nucleotides, e.g., 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, or 30 nucleotides.

In some embodiments, the RNA-programmable nuclease is a Cas9 nuclease. The RNA-programmable Cas9 endonuclease cleaves double-stranded DNA (dsDNA) at sites adjacent to a two-base-pair PAM motif and complementary to a guide RNA sequence (sgRNA). Typically, the sgRNA sequence that is complementary to the target site sequence is about 20 nucleotides long, but shorter and longer complementary sgRNA sequences can be used as well. For example, in some embodiments, the sgRNA comprises 5-50 nucleotides, 10-30 nucleotides, 15-25 nucleotides, 18-22 nucleotides, 19-21 nucleotides, e.g., 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, or 30 nucleotides. The Cas9 system has been used to modify genomes in multiple cell types, demonstrating its potential as a facile genome-engineering tool.

In some embodiments, the nuclease comprises an unspecific nucleic acid cleavage domain. In some embodiments, the nuclease comprises a FokI cleavage domain. In some embodiments, the nuclease comprises a nucleic acid cleavage domain that cleaves a target sequence upon cleavage domain dimerization. In some embodiments, the nuclease comprises a binding domain that specifically binds a nucleic acid sequence. In some embodiments, the binding domain comprises a zinc finger. In some embodiments, the binding domain comprises at least 2, at least 3, at least 4, or at least 5 zinc fingers. In some embodiments, the nuclease is a Zinc Finger Nuclease. In some embodiments, the binding domain comprises a Transcriptional Activator-Like Element. In some embodiments, the nuclease is a Transcriptional Activator-Like Element Nuclease (TALEN). In some embodiments, the nuclease is a homing endonuclease. In some embodiments, the nuclease is an organic compound. In some embodiments, the nuclease comprises an enediyne functional group. In some embodiments, the nuclease is an antibiotic. In some embodiments, the compound is dynemicin, neocarzinostatin, calicheamicin, esperamicin, bleomycin, or a derivative thereof.

Incubation of the nuclease with the library nucleic acids will result in cleavage of those concatemers in the library that comprise target sites that can be bound and cleaved by the nuclease. If a given nuclease cleaves a specific target site with high efficiency, a concatemer comprising target sites will be cut, e.g., once or multiple times, resulting in the generation of fragments comprising a cut target site adjacent to one or more repeat units. Depending on the structure of the library members, an exemplary cut nucleic acid molecule released from a library member concatemer by a single nuclease cleavage may, for example, be of the structure (cut target site)-(constant region)-[(target site)-(constant region)]_x-R₂. For example, in the context of an RNA-guided nuclease, an exemplary cut nucleic acid molecule released from a library member concatemer by a single nuclease cleavage may, for example, be of the structure (PAM)-(constant region)-[(N₂)-(PAM)-(constant region)]_x-R₂. And in the context of a nuclease cutting an LSR structure within the spacer region, an exemplary cut nucleic acid molecule released from a library member concatemer by a single nuclease cleavage may, for example, be of the structure (cut spacer region)-(right half site)-(constant region)-[(LSR)-(constant region)]_x-R₂. Such cut fragments released from library candidate molecules can then be isolated and/or the sequence of the target site cleaved by the nuclease identified by sequencing an intact target site (e.g., an intact (N₂)-(PAM) site of released repeat units. See, e.g., FIG. 1B for an illustration.

Suitable conditions for exposure of the library of nucleic acid molecules will be apparent to those of skill in the art. In some embodiments, suitable conditions do not result in denaturation of the library nucleic acids or the nuclease and allow for the nuclease to exhibit at least 50%, at least 60%, at least 70%, at least 80%, at least 90%, at least 95%, or at least 98% of its nuclease activity.

Additionally, if a given nuclease cleaves a specific target site, some cleavage products will comprise a cut half site and an intact, or uncut target site. As described herein, such products can be isolated by routine methods, and because the insert sequence, in some aspects, is less than 100 base pairs, such isolated cleavage products may be sequenced in a single read-through, allowing identification of the target site sequence without reconstructing the sequence, e.g., from cut half sites.

Any method suitable for isolation and sequencing of the repeat units can be employed to elucidate the LSR sequence cleaved by the nuclease. For example, since the length of the constant region is known, individual released repeat units can be separated based on their size from the larger uncut library nucleic acid molecules as well as from fragments of library nucleic acid molecules that comprise multiple repeat units (indicating non-efficient targeted cleavage by the nuclease). Suitable methods for separating and/or isolating nucleic acid molecules based on their size are well-known to those of skill in the art and include, for example, size fractionation methods, such as gel electrophoresis, density gradient centrifugation, and dialysis over a semi-permeable membrane with a suitable molecular cutoff value. The separated/isolated nucleic acid molecules can then be further characterized, for example, by ligating PCR and/or sequencing adapters to the cut ends and amplifying and/or sequencing the respective nucleic acids. Further, if the length of the constant region is selected to favor self-ligation of individual released repeat units, such individual released repeat units may be enriched by contacting the nuclease treated library molecules with a ligase and subsequent amplification and/or sequencing based on the circularized nature of the self-ligated individual repeat units.

In some embodiments, where a nuclease is used that generates 5'-overhangs as a result of cutting a target nucleic acid, the 5'-overhangs of the cut nucleic acid molecules are filled in. Methods for filling in 5'-overhangs are well known to those of skill in the art and include, for example, methods using DNA polymerase I Klenow fragment lacking exonuclease activity (Klenow (3'→5' exo-)). Filling in 5'-overhangs results in the overhang-templated extension of the recessed strand, which, in turn, results in blunt ends. In the case of single repeat units released from library concatemers, the resulting structure is a blunt-ended $S_2'R$ -(constant region)- LS_1' , with S_1' and S_2' comprising blunt ends. PCR and/or sequencing adapters can then be added to the ends by blunt end ligation and the respective repeat units (including $S_2'R$ and LS_1' regions) can be sequenced. From the sequence data, the original LSR region can be deduced. Blunting of the overhangs created during the nuclease cleavage process also allows for distinguishing between target sites that were properly cut by the respective nuclease and target sites that were non-specifically cut, e.g., based on non-nuclease effects such as physical shearing. Correctly cleaved nuclease target sites can be recognized by the existence of complementary $S_2'R$ and LS_1' regions, which comprise a duplication of the overhang nucleotides as a result of the overhang fill in while target sites that were not cleaved by the respective nuclease are unlikely to comprise overhang nucleotide duplications. In some embodiments, the method comprises identifying the nuclease target site cut by the nuclease by determining the sequence of the left-half site, the right-half-site, and/or the spacer sequence of a released individual repeat unit. Any suitable method for amplifying and/or sequencing can be used to identify the LSR sequence of the target site cleaved by the respective nuclease. Methods for amplifying and/or sequencing nucleic acids are well known to those of skill in the art and the disclosure is not limited in this respect. In the case of nucleic acids released from library concatemers that comprise a cut half site and an uncut target site (e.g., comprises at least about 1.5 repeat sequences), filling in the 5'-overhangs also provides for assurance that the nucleic acid was cleaved by the nuclease. Because the nucleic acid also comprises an intact, or uncut target site, the sequence of said site can be determined without having to reconstruct the sequence from a left-half site, right-half site, and/or spacer sequence.

Some of the methods and strategies provided herein allow for the simultaneous assessment of a plurality of candidate target sites as possible cleavage targets for any given nuclease. Accordingly, the data obtained from such methods can be used to compile a list of target sites cleaved by a given nuclease, which is also referred to herein as a target site profile. If a sequencing method is used that allows for the generation of quantitative sequencing data, it is also possible to record the relative abundance of any nuclease target site detected to be cleaved by the respective nuclease. Target sites that are cleaved more efficiently by the nuclease will be detected more frequently in the sequencing step, while target sites that are not cleaved efficiently will only rarely release an individual repeat unit from a candidate concatemer, and thus, will only generate few, if any, sequencing reads. Such quantitative sequencing data can be integrated into a target site profile to generate a ranked list of highly preferred and less preferred nuclease target sites.

The methods and strategies of nuclease target site profiling provided herein can be applied to any site-specific nuclease, including, for example, ZFNs, TALENs, homing endonucleases, and RNA-programmable nucleases, such as Cas9 nucleases. As described in more detail herein, nuclease specificity typically decreases with increasing nuclease concentra-

tion, and the methods described herein can be used to determine a concentration at which a given nuclease efficiently cuts its intended target site, but does not efficiently cut any off-target sequences. In some embodiments, a maximum concentration of a therapeutic nuclease is determined at which the therapeutic nuclease cuts its intended nuclease target site but does not cut more than 10, more than 5, more than 4, more than 3, more than 2, more than 1, or any additional sites. In some embodiments, a therapeutic nuclease is administered to a subject in an amount effective to generate a final concentration equal or lower than the maximum concentration determined as described above.

In some embodiments, the library of candidate nucleic acid molecules used in the methods provided herein comprises at least 10^8 , at least 10^9 , at least 10^{10} , at least 10^{11} , or at least 10^{12} different candidate nuclease target sites.

In some embodiments, the nuclease is a therapeutic nuclease which cuts a specific nuclease target site in a gene associated with a disease. In some embodiments, the method further comprises determining a maximum concentration of the therapeutic nuclease at which the therapeutic nuclease cuts the specific nuclease target site and does not cut more than 10, more than 5, more than 4, more than 3, more than 2, more than 1, or no additional sites. In some embodiments, the method further comprises administering the therapeutic nuclease to a subject in an amount effective to generate a final concentration equal or lower than the maximum concentration.

Nuclease Target Site Libraries

Some embodiments of this disclosure provide libraries of nucleic acid molecules for nuclease target site profiling. In some embodiments, the candidate nucleic acid molecules of the library comprise the structure $R_1-[(N_Z)-(PAM)-(constant\ region)]_X-R_2$, wherein R_1 and R_2 are, independently, nucleic acid sequences that may comprise a fragment of the $[(N_Z)-(PAM)-(constant\ region)]$ repeat unit; each N represents, independently, any nucleotide; Z is an integer between 1 and 50; and X is an integer between 2 and y. In some embodiments, y is at least 10^1 , at least 10^2 , at least 10^3 , at least 10^4 , at least 10^5 , at least 10^6 , at least 10^7 , at least 10^8 , at least 10^9 , at least 10^{10} , at least 10^{11} , at least 10^{12} , at least 10^{13} , at least 10^{14} , or at least 10^{15} . In some embodiments, y is less than 10^2 , less than 10^3 , less than 10^4 , less than 10^5 , less than 10^6 , less than 10^7 , less than 10^8 , less than 10^9 , less than 10^{10} , less than 10^{11} , less than 10^{12} , less than 10^{13} , less than 10^{14} , or less than 10^{15} . In some embodiments, Z is at least 2, at least 3, at least 4, at least 5, at least 6, at least 7, at least 8, at least 9, at least 10, at least 11, at least 12, at least 13, at least 14, at least 15, at least 16, at least 17, at least 18, at least 19, at least 20, at least 25, at least 30, at least 35, at least 40, at least 45, or at least 50. In some embodiments, Z is 20. Each N represents, independently, any nucleotide. Accordingly, a sequence provided as N_Z with $Z=2$ would be NN, with each N, independently, representing A, T, G, or C. Accordingly, N_Z with $Z=2$ can represent AA, AT, AG, AC, TA, TT, TG, TC, GA, GT, GG, GC, CA, CT, CG, and CC.

In some embodiments, a library is provided comprising candidate nucleic acid molecules that comprise target sites with a partially randomized left-half site, a partially randomized right-half site, and/or a partially randomized spacer sequence. In some embodiments, the library is provided comprising candidate nucleic acid molecules that comprise target sites with a partially randomized left half site, a fully randomized spacer sequence, and a partially randomized right half site. In some embodiments, a library is provided comprising candidate nucleic acid molecules that comprise target sites with a partially or fully randomized sequence, wherein the

target sites comprise the structure $[N_{\text{Z}}(\text{PAM})]$, for example as described herein. In some embodiments, partially randomized sites differ from the consensus site by more than 5%, more than 10%, more than 15%, more than 20%, more than 25%, or more than 30% on average, distributed binomially.

In some embodiments such a library comprises a plurality of nucleic acid molecules, each comprising a concatemer of a candidate nuclease target site and a constant insert sequence, also referred to herein as a constant region. For example, in some embodiments, the candidate nucleic acid molecules of the library comprise the structure $R_1\text{--}[(\text{sgRNA-complementary sequence})\text{--}(\text{PAM})\text{--}(\text{constant region})]_X\text{--}R_2$, or the structure $R_1\text{--}[(\text{LSR})\text{--}(\text{constant region})]_X\text{--}R_2$, wherein the structure in square brackets (" $[\dots]$ ") is referred to as a repeat unit or repeat sequence; R_1 and R_2 are, independently, nucleic acid sequences that may comprise a fragment of the repeat unit, and X is an integer between 2 and y . In some embodiments, y is at least 10^1 , at least 10^2 , at least 10^3 , at least 10^4 , at least 10^5 , at least 10^6 , at least 10^7 , at least 10^8 , at least 10^9 , at least 10^{10} , at least 10^{11} , at least 10^{12} , at least 10^{13} , at least 10^{14} , or at least 10^{15} . In some embodiments, y is less than 10^2 , less than 10^3 , less than 10^4 , less than 10^5 , less than 10^6 , less than 10^7 , less than 10^8 , less than 10^9 , less than 10^{10} , less than 10^{11} , less than 10^{12} , less than 10^{13} , less than 10^{14} , or less than 10^{15} . The constant region, in some embodiments, is of a length that allows for efficient self-ligation of a single repeat unit. In some embodiments, the constant region is of a length that allows for efficient separation of single repeat units from fragments comprising two or more repeat units. In some embodiments, the constant region is of a length that allows for efficient sequencing of a complete repeat unit in one sequencing read. Suitable lengths will be apparent to those of skill in the art. For example, in some embodiments, the constant region is between 5 and 100 base pairs long, for example, about 5 base pairs, about 10 base pairs, about 15 base pairs, about 20 base pairs, about 25 base pairs, about 30 base pairs, about 35 base pairs, about 40 base pairs, about 50 base pairs, about 60 base pairs, about 70 base pairs, about 80 base pairs, about 90 base pairs, or about 100 base pairs long. In some embodiments, the constant region is 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, or 80 base pairs long.

An LSR site typically comprises a [left-half site]-[spacer sequence]-[right-half site] structure. The lengths of the half-site and the spacer sequence will depend on the specific nuclease to be evaluated. In general, the half-sites will be 6-30 nucleotides long, and preferably 10-18 nucleotides long. For example, each half site individually may be 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, or 30 nucleotides long. In some embodiments, an LSR site may be longer than 30 nucleotides. In some embodiments, the left half site and the right half site of an LSR are of the same length. In some embodiments, the left half site and the right half site of an LSR are of different lengths. In some embodiments, the left half site and the right half site of an LSR are of different sequences. In some embodiments, a library is provided that comprises candidate nucleic acids which comprise LSRs that can be cleaved by a FokI cleavage domain, a Zinc Finger Nuclease (ZFN), a Transcription Activator-Like Effector Nuclease (TALEN), a homing endonuclease, or an organic compound (e.g., an enediyne antibiotic such as dynemicin, neocarzinostatin, calicheamicin, and esperamicin; and bleomycin).

In some embodiments, a library of candidate nucleic acid molecules is provided that comprises at least 10^5 , at least 10^6 , at least 10^7 , at least 10^8 , at least 10^9 , at least 10^{10} , at least 10^{11} , at least 10^{12} , at least 10^{13} , at least 10^{14} , or at least 10^{15} different candidate nuclease target sites. In some embodiments, the candidate nucleic acid molecules of the library are concatemers produced from a secularized templates by rolling cycle amplification. In some embodiments, the library comprises nucleic acid molecules, e.g., concatemers, of a molecular weight of at least 5 kDa, at least 6 kDa, at least 7 kDa, at least 8 kDa, at least 9 kDa, at least 10 kDa, at least 12 kDa, or at least 15 kDa. In some embodiments, the molecular weight of the nucleic acid molecules within the library may be larger than 15 kDa. In some embodiments, the library comprises nucleic acid molecules within a specific size range, for example, within a range of 5-7 kDa, 5-10 kDa, 8-12 kDa, 10-15 kDa, or 12-15 kDa, or 5-10 kDa or any possible sub-range. While some methods suitable for generating nucleic acid concatemers according to some aspects of this disclosure result in the generation of nucleic acid molecules of greatly different molecular weights, such mixtures of nucleic acid molecules may be size fractionated to obtain a desired size distribution. Suitable methods for enriching nucleic acid molecules of a desired size or excluding nucleic acid molecules of a desired size are well known to those of skill in the art and the disclosure is not limited in this respect.

In some embodiments, partially randomized sites differ from the consensus site by no more than 10%, no more than 15%, no more than 20%, no more than 25%, nor more than 30%, no more than 40%, or no more than 50% on average, distributed binomially. For example, in some embodiments partially randomized sites differ from the consensus site by more than 5%, but by no more than 10%; by more than 10%, but by no more than 20%; by more than 20%, but by no more than 25%; by more than 5%, but by no more than 20%, and so on. Using partially randomized nuclease target sites in the library is useful to increase the concentration of library members comprising target sites that are closely related to the consensus site, for example, that differ from the consensus sites in only one, only two, only three, only four, or only five residues. The rationale behind this is that a given nuclease, for example a given ZFN or RNA-programmable nuclease, is likely to cut its intended target site and any closely related target sites, but unlikely to cut a target sites that is vastly different from or completely unrelated to the intended target site. Accordingly, using a library comprising partially randomized target sites can be more efficient than using libraries comprising fully randomized target sites without compromising the sensitivity in detecting any off-target cleavage events for any given nuclease. Thus, the use of partially randomized libraries significantly reduces the cost and effort required to produce a library having a high likelihood of covering virtually all off-target sites of a given nuclease. In some embodiments however it may be desirable to use a fully randomized library of target sites, for example, in embodiments, where the specificity of a given nuclease is to be evaluated in the context of any possible site in a given genome.

Selection and Design of Site-Specific Nucleases

Some aspects of this disclosure provide methods and strategies for selecting and designing site-specific nucleases that allow the targeted cleavage of a single, unique sites in the context of a complex genome. In some embodiments, a method is provided that comprises providing a plurality of candidate nucleases that are designed or known to cut the same consensus sequence; profiling the target sites actually cleaved by each candidate nuclease, thus detecting any cleaved off-target sites (target sites that differ from the con-

sensus target site); and selecting a candidate nuclease based on the off-target site(s) so identified. In some embodiments, this method is used to select the most specific nuclease from a group of candidate nucleases, for example, the nuclease that cleaves the consensus target site with the highest specificity, the nuclease that cleaves the lowest number of off-target sites in the context of a target genome, or a nuclease that does not cleave any target site other than the consensus target site. In some embodiments, this method is used to select a nuclease that does not cleave any off-target site in the context of the genome of a subject at concentration that is equal to or higher than a therapeutically effective concentration of the nuclease.

The methods and reagents provided herein can be used, for example, to evaluate a plurality of different nucleases targeting the same intended targets site, for example, a plurality of variations of a given site-specific nuclease, for example a given zinc finger nuclease. Accordingly, such methods may be used as the selection step in evolving or designing a novel site-specific nucleases with improved specificity.

Identifying Unique Nuclease Target Sites within a Genome

Some embodiments of this disclosure provide a method for selecting a nuclease target site within a genome. As described in more detail elsewhere herein, it was surprisingly discovered that off target sites cleaved by a given nuclease are typically highly similar to the consensus target site, e.g., differing from the consensus target site in only one, only two, only three, only four, or only five nucleotide residues. Based on this discovery, a nuclease target sites within the genome can be selected to increase the likelihood of a nuclease targeting this site not cleaving any off target sites within the genome. For example, in some embodiments, a method is provided that comprises identifying a candidate nuclease target site; and comparing the candidate nuclease target site to other sequences within the genome. Methods for comparing candidate nuclease target sites to other sequences within the genome are well known to those of skill in the art and include for example sequence alignment methods, for example, using a sequence alignment software or algorithm such as BLAST on a general purpose computer. A suitable unique nuclease target site can then be selected based on the results of the sequence comparison. In some embodiments, if the candidate nuclease target site differs from any other sequence within the genome by at least 3, at least 4, at least 5, at least 6, at least 7, at least 8, at least 9, or at least 10 nucleotides, the nuclease target site is selected as a unique site within the genome, whereas if the site does not fulfill this criteria, the site may be discarded. In some embodiments, once a site is selected based on the sequence comparison, as outlined above, a site-specific nuclease targeting the selected site is designed. For example, a zinc finger nuclease may be designed to target any selected nuclease target site by constructing a zinc finger array binding the target site, and conjugating the zinc finger array to a DNA cleavage domain. In embodiments where the DNA cleavage domain needs to dimerize in order to cleave DNA, to zinc finger arrays will be designed, each binding a half site of the nuclease target site, and each conjugated to a cleavage domain. In some embodiments, nuclease designing and/or generating is done by recombinant technology. Suitable recombinant technologies are well known to those of skill in the art, and the disclosure is not limited in this respect.

In some embodiments, a site-specific nuclease designed or generated according to aspects of this disclosure is isolated and/or purified. The methods and strategies for designing site-specific nucleases according to aspects of this disclosure can be applied to design or generate any site-specific nuclease, including, but not limited to Zinc Finger Nucleases,

Transcription Activator-Like Effector Nucleases (TALENs), a homing endonuclease, an organic compound nuclease, or an enediyne antibiotic (e.g., dynemicin, neocarzinostatin, calicheamicin, esperamicin, bleomycin).

Isolated Nucleases

Some aspects of this disclosure provide isolated site-specific nucleases with enhanced specificity that are designed using the methods and strategies described herein. Some embodiments, of this disclosure provide nucleic acids encoding such nucleases. Some embodiments of this disclosure provide expression constructs comprising such encoding nucleic acids. For example, in some embodiments an isolated nuclease is provided that has been engineered to cleave a desired target site within a genome, and has been evaluated according to a method provided herein to cut less than 1, less than 2, less than 3, less than 4, less than 5, less than 6, less than 7, less than 8, less than 9 or less than 10 off-target sites at a concentration effective for the nuclease to cut its intended target site. In some embodiments an isolated nuclease is provided that has been engineered to cleave a desired unique target site that has been selected to differ from any other site within a genome by at least 3, at least 4, at least 5, at least 6, at least 7, at least 8, at least 9, or at least 10 nucleotide residues. In some embodiments, the isolated nuclease is an RNA-programmable nuclease, such as a Cas9 nuclease; a Zinc Finger Nuclease (ZFN); or a Transcription Activator-Like Effector Nuclease (TALEN), a homing endonuclease, an organic compound nuclease, or an enediyne antibiotic (e.g., dynemicin, neocarzinostatin, calicheamicin, esperamicin, bleomycin). In some embodiments, the isolated nuclease cleaves a target site within an allele that is associated with a disease or disorder. In some embodiments, the isolated nuclease cleaves a target site the cleavage of which results in treatment or prevention of a disease or disorder. In some embodiments, the disease is HIV/AIDS, or a proliferative disease. In some embodiments, the allele is a CCR5 (for treating HIV/AIDS) or a VEGFA allele (for treating a proliferative disease).

In some embodiments, the isolated nuclease is provided as part of a pharmaceutical composition. For example, some embodiments provide pharmaceutical compositions comprising a nuclease as provided herein, or a nucleic acid encoding such a nuclease, and a pharmaceutically acceptable excipient. Pharmaceutical compositions may optionally comprise one or more additional therapeutically active substances.

In some embodiments, compositions provided herein are administered to a subject, for example, to a human subject, in order to effect a targeted genomic modification within the subject. In some embodiments, cells are obtained from the subject and contacted with a nuclease or a nuclease-encoding nucleic acid ex vivo, and re-administered to the subject after the desired genomic modification has been effected or detected in the cells. Although the descriptions of pharmaceutical compositions provided herein are principally directed to pharmaceutical compositions which are suitable for administration to humans, it will be understood by the skilled artisan that such compositions are generally suitable for administration to animals of all sorts. Modification of pharmaceutical compositions suitable for administration to humans in order to render the compositions suitable for administration to various animals is well understood, and the ordinarily skilled veterinary pharmacologist can design and/or perform such modification with merely ordinary, if any, experimentation. Subjects to which administration of the pharmaceutical compositions is contemplated include, but are not limited to, humans and/or other primates; mammals,

including commercially relevant mammals such as cattle, pigs, horses, sheep, cats, dogs, mice, and/or rats; and/or birds, including commercially relevant birds such as chickens, ducks, geese, and/or turkeys.

Formulations of the pharmaceutical compositions described herein may be prepared by any method known or hereafter developed in the art of pharmacology. In general, such preparatory methods include the step of bringing the active ingredient into association with an excipient and/or one or more other accessory ingredients, and then, if necessary and/or desirable, shaping and/or packaging the product into a desired single- or multi-dose unit.

Pharmaceutical formulations may additionally comprise a pharmaceutically acceptable excipient, which, as used herein, includes any and all solvents, dispersion media, diluents, or other liquid vehicles, dispersion or suspension aids, surface active agents, isotonic agents, thickening or emulsifying agents, preservatives, solid binders, lubricants and the like, as suited to the particular dosage form desired. Remington's *The Science and Practice of Pharmacy*, 21st Edition, A. R. Gennaro (Lippincott, Williams & Wilkins, Baltimore, Md., 2006; incorporated in its entirety herein by reference) discloses various excipients used in formulating pharmaceutical compositions and known techniques for the preparation thereof. See also PCT application PCT/US2010/055131, incorporated in its entirety herein by reference, for additional suitable methods, reagents, excipients and solvents for producing pharmaceutical compositions comprising a nuclease. Except insofar as any conventional excipient medium is incompatible with a substance or its derivatives, such as by producing any undesirable biological effect or otherwise interacting in a deleterious manner with any other component (s) of the pharmaceutical composition, its use is contemplated to be within the scope of this disclosure.

The function and advantage of these and other embodiments of the present invention will be more fully understood from the Examples below. The following Examples are intended to illustrate the benefits of the present invention and to describe particular embodiments, but are not intended to exemplify the full scope of the invention. Accordingly, it will be understood that the Examples are not meant to limit the scope of the invention.

EXAMPLES

Materials and Methods

Oligonucleotides. All oligonucleotides used in this study were purchased from Integrated DNA Technologies. Oligonucleotide sequences are listed in Table 9.

Expression and Purification of *S. pyogenes* Cas9. *E. coli* Rosetta (DE3) cells were transformed with plasmid pMJ806¹¹, encoding the *S. pyogenes* cas9 gene fused to an N-terminal 6× His-tag/maltose binding protein. The resulting expression strain was inoculated in Luria-Bertani (LB) broth containing 100 µg/mL of ampicillin and 30 µg/mL of chloramphenicol at 37° C. overnight. The cells were diluted 1:100 into the same growth medium and grown at 37° C. to OD₆₀₀ ~0.6. The culture was incubated at 18° C. for 30 min, and isopropyl β-D-1-thiogalactopyranoside (IPTG) was added at 0.2 mM to induce Cas9 expression. After ~17 h, the cells were collected by centrifugation at 8,000 g and resuspended in lysis buffer (20 mM tris(hydroxymethyl)-aminomethane (Tris)-HCl, pH 8.0, 1 M KCl, 20% glycerol, 1 mM tris(2-carboxyethyl)phosphine (TCEP)). The cells were lysed by sonication (10 sec pulse-on and 30 sec pulse-off for 10 min total at 6 W output) and the soluble lysate was obtained by centrifugation at 20,000 g for 30 min. The cell lysate was

incubated with nickel-nitriloacetic acid (nickel-NTA) resin (Qiagen) at 4° C. for 20 min to capture His-tagged Cas9. The resin was transferred to a 20-mL column and washed with 20 column volumes of lysis buffer. Cas9 was eluted in 20 mM Tris-HCl (pH 8), 0.1 M KCl, 20% glycerol, 1 mM TCEP, and 250 mM imidazole, and concentrated by Amicon ultra centrifugal filter (Millipore, 30-kDa molecular weight cut-off) to ~50 mg/mL. The 6× His tag and maltose-binding protein were removed by TEV protease treatment at 4° C. for 20 h and captured by a second Ni-affinity purification step. The eluent, containing Cas9, was injected into a HiTrap SP FF column (GE Healthcare) in purification buffer containing 20 mM Tris-HCl (pH 8), 0.1 M KCl, 20% glycerol, and 1 mM TCEP. Cas9 was eluted with purification buffer containing a linear KCl gradient from 0.1 M to 1 M over five column volumes. The eluted Cas9 was further purified by a HiLoad Superdex 200 column in purification buffer, snap-frozen in liquid nitrogen, and stored in aliquots at -80° C.

In Vitro RNA Transcription. 100 pmol CLTA(♯) v2.1 fwd and v2.1 template rev were incubated at 95° C. and cooled at 0.1° C./s to 37° C. in NEBuffer2 (50 mM sodium chloride, 10 mM Tris-HCl, 10 mM magnesium chloride, 1 mM dithiothreitol, pH 7.9) supplemented with 10 µM dNTP mix (Bio-Rad). 10 U of Klenow Fragment (3'→5' exo⁻) (NEB) were added to the reaction mixture and a double-stranded CLTA(♯) v2.1 template was obtained by overlap extension for 1 h at 37° C. 200 nM CLTA(♯) v2.1 template alone or 100 nM CLTA(♯) template with 100 nM T7 promoter oligo was incubated overnight at 37° C. with 0.16 U/µL of T7 RNA Polymerase (NEB) in NEB RNAPol Buffer (40 mM Tris-HCl, pH 7.9, 6 mM magnesium chloride, 10 mM dithiothreitol, 2 mM spermidine) supplemented with 1 mM rNTP mix (1 mM rATP, 1 mM rCTP, 1 mM rGTP, 1 mM rUTP). In vitro transcribed RNA was precipitated with ethanol and purified by gel electrophoresis on a Criterion 10% polyacrylamide TBE-Urea gel (Bio-Rad). Gel-purified sgRNA was precipitated with ethanol and redissolved in water.

In Vitro Library Construction. 10 pmol of CLTA(♯) lib oligonucleotides were separately circularized by incubation with 100 units of CircLigase II ssDNA Ligase (Epicentre) in 1× CircLigase II Reaction Buffer (33 mM Tris-acetate, 66 mM potassium acetate, 0.5 mM dithiothreitol, pH 7.5) supplemented with 2.5 mM manganese chloride in a total reaction volume of 20 µL for 16 hours at 60° C. The reaction mixture was incubated for 10 minutes at 85° C. to inactivate the enzyme. 5 µL (5 pmol) of the crude circular single-stranded DNA were converted into the concatemeric pre-selection libraries with the illustra TempliPhi Amplification Kit (GE Healthcare) according to the manufacturer's protocol. Concatemeric pre-selection libraries were quantified with the Quant-it PicoGreen dsDNA Assay Kit (Invitrogen).

In Vitro Cleavage of on-Target and Off-Target Substrates. Plasmid templates for PCR were constructed by ligation of annealed oligonucleotides CLTA(♯) site fwd/rev into HindIII/XbaI double-digested pUC19 (NEB). On-target substrate DNAs were generated by PCR with the plasmid templates and test fwd and test rev primers, then purified with the QIAquick PCR Purification Kit (Qiagen). Off-target substrate DNAs were generated by primer extension. 100 pmol off-target (♯) fwd and off-target (♯) rev primers were incubated at 95° C. and cooled at 0.1° C./s to 37° C. in NEBuffer2 (50 mM sodium chloride, 10 mM Tris-HCl, 10 mM magnesium chloride, 1 mM dithiothreitol, pH 7.9) supplemented with 10 µM dNTP mix (Bio-Rad). 10 U of Klenow Fragment (3'→5' exo⁻) (NEB) were added to the reaction mixture and double-stranded off-target templates were obtained by overlap extension for 1 h at 37° C. followed by enzyme inactivation.

tion for 20 min at 75° C., then purified with the QIAquick PCR Purification Kit (Qiagen). 200 nM substrate DNAs were incubated with 100 nM Cas9 and 100 nM (v1.0 or v2.1) sgRNA or 1000 nM Cas9 and 1000 nM (v1.0 or v2.1) sgRNA in Cas9 cleavage buffer (200 mM HEPES, pH 7.5, 1.5 M potassium chloride, 100 mM magnesium chloride, 1 mM EDTA, 5 mM dithiothreitol) for 10 min at 37° C. On-target cleavage reactions were purified with the QIAquick PCR Purification Kit (Qiagen), and off-target cleavage reactions were purified with the QIAquick Nucleotide Removal Kit (Qiagen) before electrophoresis in a Criterion 5% polyacrylamide TBE gel (Bio-Rad).

In Vitro Selection. 200 nM concatemeric pre-selection libraries were incubated with 100 nM Cas9 and 100 nM sgRNA or 1000 nM Cas9 and 1000 nM sgRNA in Cas9 cleavage buffer (200 mM HEPES, pH 7.5, 1.5 M potassium chloride, 100 mM magnesium chloride, 1 mM EDTA, 5 mM dithiothreitol) for 10 min at 37° C. Pre-selection libraries were also separately incubated with 2 U of BspMI restriction endonuclease (NEB) in NEBuffer 3 (100 mM NaCl, 50 mM Tris-HCl, 10 mM MgCl₂, 1 mM dithiothreitol, pH 7.9) for 1 h at 37° C. Blunt-ended post-selection library members or sticky-ended pre-selection library members were purified with the QIAquick PCR Purification Kit (Qiagen) and ligated to 10 pmol adapter1/2(AACA) (Cas9:v2.1 sgRNA, 100 nM), adapter1/2(TTCA) (Cas9:v2.1 sgRNA, 1000 nM), adapter1/2 (Cas9:v2.1 sgRNA, 1000 nM), or lib adapter1/CLTA(#) lib adapter 2 (pre-selection) with 1,000 U of T4 DNA Ligase (NEB) in NEB T4 DNA Ligase Reaction Buffer (50 mM Tris-HCl, pH 7.5, 10 mM magnesium chloride, 1 mM ATP, 10 mM dithiothreitol) overnight (>10 h) at room temperature. Adapter-ligated DNA was purified with the QIAquick PCR Purification Kit and PCR-amplified for 10-13 cycles with Phusion Hot Start Flex DNA Polymerase (NEB) in Buffer HF (NEB) and primers CLTA(#) sel PCR/PE2 short (post-selection) or CLTA(#) lib seq PCR/lib fwd PCR (pre-selection). Amplified DNAs were gel purified, quantified with the KAPA Library Quantification Kit-Illumina (KAPA Biosystems), and subjected to single-read sequencing on an Illumina MiSeq or Rapid Run single-read sequencing on an Illumina HiSeq 2500 (Harvard University FAS Center for Systems Biology Core facility, Cambridge, Mass.).

Selection Analysis. Pre-selection and post-selection sequencing data were analyzed as previously described²¹, with modification (Algorithms) using scripts written in C++. Raw sequence data is not shown; see Table 2 for a curated summary. Specificity scores were calculated with the formulae: positive specificity score=(frequency of base pair at position[post-selection]-frequency of base pair at position[pre-selection])/(1-frequency of base pair at position[pre-selection]) and negative specificity score=(frequency of base pair at position[post-selection]-frequency of base pair at position[pre-selection])/(frequency of base pair at position[pre-selection]). Normalization for sequence logos was performed as previously described²².

Cellular Cleavage Assays. HEK293T cells were split at a density of 0.8×10⁵ per well (6-well plate) before transcription and maintained in Dulbecco's modified eagle medium (DMEM) supplemented with 10% fetal bovine serum (FBS) in a 37° C. humidified incubator with 5% CO₂. After 1 day, cells were transiently transfected using Lipofectamine 2000 (Invitrogen) following the manufacturer's protocols. HEK293T cells were transfected at 70% confluency in each well of 6-well plate with 1.0 µg of the Cas9 expression plasmid (Cas9-HA-2×NLS-GFP-NLS) and 2.5 µg of the single-strand RNA expression plasmid pSilencer-CLTA (version 1.0 or 2.1). The transfection efficiencies were estimated to be

~70%, based on the fraction of GFP-positive cells observed by fluorescence microscopy. 48 h after transfection, cells were washed with phosphate buffered saline (PBS), pelleted and frozen at -80° C. Genomic DNA was isolated from 200 µL cell lysate using the DNeasy Blood and Tissue Kit (Qiagen) according to the manufacturer's protocol.

Off-Target Site Sequence Determination. 100 ng genomic DNA isolated from cells treated with Cas9 expression plasmid and single-strand RNA expression plasmid (treated cells) or Cas9 expression plasmid alone (control cells) were amplified by PCR with 10 s 72° C. extension for 35 cycles with primers CLTA(#)-(#)-(#) fwd and CLTA(#)-(#)-(#) rev and Phusion Hot Start Flex DNA Polymerase (NEB) in Buffer GC (NEB), supplemented with 3% DMSO. Relative amounts of crude PCR products were quantified by gel, and Cas9-treated (control) and Cas9:sgRNA-treated PCRs were separately pooled in equimolar concentrations before purification with the QIAquick PCR Purification Kit (Qiagen). Purified DNA was amplified by PCR with primers PE1-barcode# and PE2-barcode# for 7 cycles with Phusion Hot Start Flex DNA Polymerase (NEB) in Buffer HF (NEB). Amplified control and treated DNA pools were purified with the QIAquick PCR Purification Kit (Qiagen), followed by purification with Agencourt AMPure XP (Beckman Coulter). Purified control and treated DNAs were quantified with the KAPA Library Quantification Kit-Illumina (KAPA Biosystems), pooled in a 1:1 ratio, and subjected to paired-end sequencing on an Illumina MiSeq.

Statistical Analysis. Statistical analysis was performed as previously described²¹. P-values in Table 1 and Table 6 were calculated for a one-sided Fisher exact test.

Algorithms

All scripts were written in C++. Algorithms used in this study are as previous reported (reference) with modification.

Sequence binning. 1) designate sequence pairs starting with the barcode "AACA" or "TTCA" as post-selection library members. 2) for post-selection library members (with illustrated example):

Example Read:

```
(SEQ ID NO: 42)
AACACATGGGTCGACACAAACACAACTCGGCAGGTACTTCAGATGTAGT
CTTCCACATGGGTCGACACAAACACAACTCGGCAGGTATCTCGTATGCC
```

i) search both paired reads for the positions, pos1 and pos2, of the constant sequence "CTCGGCAGGT" (SEQ ID NO:43). ii) keep only sequences that have identical sequences between the barcode and pos1 and preceding pos2. iii) keep the region between the two instances of the constant sequence (the region between the barcode and pos1 contains a cut half-site; the region that is between the two instances of the constant sequence contains a full site)

Example:

```
(SEQ ID NO: 44)
ACTTCGAGATGTAGTCTTCCACATGGGTCGACACAAACACAA
```

ii) search the sequence for a selection barcode ("TGIGTTTGTGTT" (SEQ ID NO:45) for CLTA1, "AGAAGAAGAAGA" (SEQ ID NO:46) for CLTA2, "TTCTCTTCTCT" (SEQ ID NO:47) for CLTA3, "ACACAAACACAA" (SEQ ID NO:48) for CLTA4)

Example:

(SEQ ID NO: 49)
ACTTGCAGATGTAGTCTTTCCACATGGGTCGACACAAACACAA-

CLTA4

iii) the sequence before the barcode is the full post-selection library member (first four and last four nucleotides are fully randomized flanking sequence)

Example:

(SEQ ID NO: 50)
ACTT GCAGATGTAGTCTTTCCACATGG GTCG

- iv) parse the quality scores for the positions corresponding to the 23 nucleotide post-selection library member

Example Read:

(SEQ ID NO: 51)

AACACATGGGTCGCACAAACACAACCTCGGCAGGTACTTGCAGATGTAGT
CTTTCCACATGGGTCGCACAAACACAACCTCGGCAGGTATCTCGTATGCC
CCCCFFFFHHHHHJJJJJJJJJJJJJJJJJJJJJJJJJJJJJJJJJJJJIIH

I I J J H H H G H A E F C D D D D D D D D D D D D D D D D D D ? C D D E D D

@DCCCD

v) keep sequences only if the corresponding quality score string (underlined) FASTQ quality characters for the sequence are “?” or higher in ASCII code (Phred quality score ≥ 30)

NHEJ Sequence Calling

Example Read:

(SEQ ID NO: 52)

CAATCTCCCGCATGCGCTCAGTCTCTATCTCCCTCAAGCAGGCCCGCTG

GTGCACTGAAGAGCCACCCCTGTGAAACACTACATCTGCAATATCTTAATC

CTACTCAGTGAAGCTCTTCACAGTCATTGGATTAATTATGTTGAGTCTTT

TTGGACCAAAACC

Example Quality Scores:

[illegible]

1) identify the 20 base pairs flanking both sides of 20 base pair target site+three base pair PAM for each target site

Example Flanking Sequences:

(SEQ ID NO: 53)
GCTGGTGCCTGAAGAGCCA

(SEQ ID NO: 54)
AATATCTTAATCCTACTCAG

- 2) search all sequence reads for the flanking sequences to identify the potential off-target site (the sequence between the flanking sequences)

Example Potential Off-target Site:

(SEQ ID NO: 55)
CCCTGTGAAACACTACATCTGC

- 3) if the potential off-target site contains indels (length is less than 23), keep sequence as potential off-target site if all corresponding FASTQ quality characters for the sequence are '?' or higher in ASCII code (Phred quality score ≥ 30)

Example Potential Off-target Site Length=22

example corresponding FASTQ quality characters:
HHHHHHHHHHHHHHHHHHHHHHHHHHHHHH

4) bin and manually inspect all sequences that pass steps 2 and 3 and keep sequences as potential modified sequences if they have at least one deletion involving position 16, 17, or 18 (of 20 counting from the non-PAM end) or if they have an insertion between position 17 and 18, consistent with the most frequent modifications observed for the intended target site (FIG. 3)

Example Potential Off-target Site (Reverse Complement, with Positions Labeled) with Reference Sequence:

```

                                11111111112222
non-PAM end 12345678901234567890123 PAM end

```

GCAGATGTAGTGTTTC-ACAGGG (SEQ ID NO: 56)

GCAGATGTAGTGTTTCCACAGGG (SEO ID NO: 57)

4) repeat steps 1-3 for read2 and keep only if the sequence is the same

5) compare overall counts in Cas9+sgRNA treated sample to Cas9 alone sample to identify modified sites

Filter Based on Cleavage Site (for Post-selection Sequences)

- 1) tabulate the cleavage site locations across the recognition site by identifying the first position in the full sequenced recognition site (between the two constant sequences) that is identical to the first position in the sequencing read after the barcode (before the first constant sequence).

- 2) after tabulation, repeat step 1, keeping only sequences with cleavage site locations that are present in at least 5% of the sequencing reads.

Results

Broad Off-target DNA Cleavage Profiling Reveals RNA-programmed Cas9 Nuclease Specificity.

Sequence-specific endonucleases including zinc-finger nucleases (ZFNs) and transcription activator-like effector nucleases (TALENs) have become important tools to modify genes in induced pluripotent stem cells (iPSCs),¹⁻³ in multicellular organisms,⁴⁻⁸ and in *ex vivo* gene therapy clinical trials.^{9, 10} Although ZFNs and TALENs have proved effective for such genetic manipulation, a new ZFN or TALEN protein must be generated for each DNA target site. In contrast, the RNA-guided Cas9 endonuclease uses RNA:DNA hybridization to determine target DNA cleavage sites, enabling a single monomeric protein to cleave, in principle, any sequence specified by the guide RNA.¹¹

Previous studies¹²⁻¹⁷ demonstrated that Cas9 mediates genome editing at sites complementary to a 20-nucleotide sequence in a bound guide RNA. In addition, target sites must include a protospacer adjacent motif (PAM) at the 3' end adjacent to the 20-nucleotide target site; for *Streptococcus*

pyogenes Cas9, the PAM sequence is NGG. Cas9-mediated DNA cleavage specificity both in vitro and in cells has been inferred previously based on assays against small collections of potential single-mutation off-target sites. These studies suggested that perfect complementarity between guide RNA and target DNA is required in the 7-12 base pairs adjacent to the PAM end of the target site (3' end of the guide RNA) and mismatches are tolerated at the non-PAM end (5' end of the guide RNA).^{11, 12, 17-19}

Although such a limited number of nucleotides specifying Cas9:guide RNA target recognition would predict multiple sites of DNA cleavage in genomes of moderate to large size ($>10^7$ bp), Cas9:guide RNA complexes have been successfully used to modify both cells^{12, 13, 15} and organisms.¹⁴ A study using Cas9:guide RNA complexes to modify zebrafish embryos observed toxicity at a rate similar to that of ZFNs and TALENs.¹⁴ A recent, broad study of the specificity of DNA binding (transcriptional repression) in *E. coli* of a catalytically inactive Cas9 mutant using high-throughput sequencing found no detectable off-target transcriptional repression in the relatively small *E. coli* transcriptome.²⁰ While these studies have substantially advanced our basic understanding of Cas9, a systematic and comprehensive profile of Cas9:guide RNA-mediated DNA cleavage specificity generated from measurements of Cas9 cleavage on a large number of related mutant target sites has not been described. Such a specificity profile is needed to understand and improve the potential of Cas9:guide RNA complexes as research tools and future therapeutic agents.

We modified our previously published in vitro selection,²¹ adapted to process the blunt-ended cleavage products produced by Cas9 compared to the overhang-containing products of ZFN cleavage, to determine the off-target DNA cleavage profiles of Cas9:single guide RNA (sgRNA)¹¹ complexes. Each selection experiment used DNA substrate libraries containing $\sim 10^{12}$ sequences, a size sufficiently large to include ten-fold coverage of all sequences with eight or fewer mutations relative to each 22-base pair target sequence (including the two-base pair PAM) (FIG. 1). We used partially randomized nucleotide mixtures at all 22 target-site base pairs to create a binomially distributed library of mutant target sites with an expected mean of 4.62 mutations per target site. In addition, target site library members were flanked by four fully randomized base pairs on each side to test for specificity patterns beyond those imposed by the canonical 20-base pair target site and PAM.

Pre-selection libraries of 10^{12} individual potential off-target sites were generated for each of four different target sequences in the human clathrin light chain A (CLTA) gene (FIG. 3). Synthetic 5'-phosphorylated 53-base oligonucleotides were self-ligated into circular single-stranded DNA in vitro, then converted into concatemeric 53-base pair repeats through rolling-circle amplification. The resulting pre-selection libraries were incubated with their corresponding Cas9:sgRNA complexes. Cleaved library members containing free 5' phosphates were separated from intact library members through the 5' phosphate-dependent ligation of non-phosphorylated double-stranded sequencing adapters. The ligation-tagged post-selection libraries were amplified by PCR. The PCR step generated a mixture of post-selection DNA fragments containing 0.5, 1.5, or 2.5, etc. repeats of library members cleaved by Cas9, resulting from amplification of an adapter-ligated cut half-site with or without one or more adjacent corresponding full sites (FIG. 1). Post-selection library members with 1.5 target-sequence repeats were isolated by gel purification and analyzed by high-throughput sequencing. In a final computational selection step to mini-

mize the impact of errors during DNA amplification or sequencing, only sequences with two identical copies of the repeated cut half-site were analyzed.

Pre-selection libraries were incubated under enzyme-limiting conditions (200 nM target site library, 100 nM Cas9:sgRNA v2.1) or enzyme-saturating conditions (200 nM target site library, 1000 nM Cas9:sgRNA v2.1) for each of the four guide RNAs targets tested (CLTA1, CLTA2, CLTA3, and CLTA4) (FIGS. 3C and 3D). A second guide RNA construct, sgRNA v1.0, which is less active than sgRNA v2.1, was assayed under enzyme-saturating conditions alone for each of the four guide RNA targets tested (200 nM target site library, 1000 nM Cas9:sgRNA v1.0). The two guide RNA constructs differ in their length (FIG. 3) and in their DNA cleavage activity level under the selection conditions, consistent with previous reports¹⁵ (FIG. 4). Both pre-selection and post-selection libraries were characterized by high-throughput DNA sequencing and computational analysis. As expected, library members with fewer mutations were significantly enriched in post-selection libraries relative to pre-selection libraries (FIG. 5).

Pre- and Post-Selection Library Composition. The pre-selection libraries for CLTA1, CLTA2, CLTA3, and CLTA4 had observed mean mutation rates of 4.82 (n=1,129,593), 5.06 (n=847,618), 4.66 (n=692,997), and 5.00 (n=951,503) mutations per 22-base pair target site, including the two-base pair PAM, respectively. The post-selection libraries treated under enzyme-limiting conditions with Cas9 plus CLTA1, CLTA2, CLTA3, or CLTA4 v2.1 sgRNAs contained means of 1.14 (n=1,206,268), 1.21 (n=668,312), 0.91 (n=1,138,568), and 1.82 (n=560,758) mutations per 22-base pair target site. Under enzyme-excess conditions, the mean number of mutations among sequences surviving selection increased to 1.61 (n=640,391), 1.86 (n=399,560), 1.46 (n=936,414), and 2.24 (n=506,179) mutations per 22-base pair target site, respectively, for CLTA1, CLTA2, CLTA3, or CLTA4 v2.1 sgRNAs. These results reveal that the selection significantly enriched library members with fewer mutations for all Cas9:sgRNA complexes tested, and that enzyme-excess conditions resulted in the putative cleavage of more highly mutated library members compared with enzyme-limiting conditions (FIG. 5).

We calculated specificity scores to quantify the enrichment level of each base pair at each position in the post-selection library relative to the pre-selection library, normalized to the maximum possible enrichment of that base pair. Positive specificity scores indicate base pairs that were enriched in the post-selection library and negative specificity scores indicate base pairs that were de-enriched in the post-selection library. For example, a score of +0.5 indicates that a base pair is enriched to 50% of the maximum enrichment value, while a score of -0.5 indicates that a base pair is de-enriched to 50% of the maximum de-enrichment value.

In addition to the two base pairs specified by the PAM, all 20 base pairs targeted by the guide RNA were enriched in the sequences from the CLTA1 and CLTA2 selections (FIG. 2, FIGS. 6 and 9, and Table 2). For the CLTA3 and CLTA4 selections (FIGS. 7 and 8, and Table 2), guide RNA-specified base pairs were enriched at all positions except for the two most distal base pairs from the PAM (5' end of the guide RNA), respectively. At these non-specified positions farthest from the PAM, at least two of the three alternate base pairs were nearly as enriched as the specified base pair. Our finding that the entire 20 base-pair target site and two base pair PAM can contribute to Cas9:sgRNA DNA cleavage specificity can

trasts with the results from previous single-substrate assays suggesting that only 7-12 base pairs and two base pair PAM are specified.^{11, 12, 15}

All single-mutant pre-selection ($n \geq 14,569$) and post-selection library members ($n \geq 103,660$) were computationally analyzed to provide a selection enrichment value for every possible single-mutant sequence. The results of this analysis (FIG. 2 and FIGS. 6 and 8) show that when only single-mutant sequences are considered, the six to eight base pairs closest to the PAM are generally highly specified and the non-PAM end is poorly specified under enzyme-limiting conditions, consistent with previous findings.^{11, 12, 17-19} Under enzyme-saturating conditions, however, single mutations even in the six to eight base pairs most proximal to the PAM end of the DNA target site can be compromised when enzyme concentrations are high relative to substrate (FIG. 2). The observation of high specificity against single mutations close to the PAM only applies to sequences with a single mutation and the selection results do not support a model in which any combination of mutations is tolerated in the region of the target site farthest from the PAM (FIG. 10-15). Analyses of pre- and post-selection library composition are described elsewhere herein, position-dependent specificity patterns are illustrated in FIGS. 18-20, PAM nucleotide specificity is illustrated in FIGS. 21-24, and more detailed effects of Cas9:sgRNA concentration on specificity are described in FIG. 2G and FIG. 25).

Specificity at the Non-PAM End of the Target Site. To assess the ability of Cas9:v2.1 sgRNA under enzyme-excess conditions to tolerate multiple mutations distal to the PAM, we calculated maximum specificity scores at each position for sequences that contained mutations only in the region of one to 12 base pairs at the end of the target site most distal from the PAM (FIG. 10-17).

The results of this analysis show no selection (maximum specificity score ~ 0) against sequences with up to three mutations, depending on the target site, at the end of the molecule farthest from the PAM when the rest of the sequence contains no mutations. For example, when only the three base pairs farthest from the PAM are allowed to vary (indicated by dark bars in FIG. 11C) in the CLTA2 target site, the maximum specificity scores at each of the three variable positions are close to zero, indicating that there was no selection for any of the four possible base pairs at each of the three variable positions. However, when the eight base pairs farthest from the PAM are allowed to vary (FIG. 11H), the maximum specificity scores at positions 4-8 are all greater than $+0.4$, indicating that the Cas9:sgRNA has a sequence preference at these positions even when the rest of the substrate contains preferred, on-target base pairs.

We also calculated the distribution of mutations (FIG. 15-17), in both pre-selection and v2.1 sgRNA-treated post-selection libraries under enzyme-excess conditions, when only the first 1-12 base pairs of the target site are allowed to vary. There is significant overlap between the pre-selection and post-selection libraries for only a subset of the data (FIG. 15-17, *a-c*), demonstrating minimal to no selection in the post-selection library for sequences with mutations only in the first three base pairs of the target site. These results collectively show that Cas9:sgRNA can tolerate a small number of mutations (\sim one to three) at the end of the sequence farthest from the PAM when provided with maximal sgRNA:DNA interactions in the rest of the target site.

Specificity at the PAM End of the Target Site. We plotted positional specificity as the sum of the magnitudes of the specificity scores for all four base pairs at each position of

each target site, normalized to the same sum for the most highly specified position (FIG. 18-20). Under both enzyme-limiting and enzyme-excess conditions, the PAM end of the target site is highly specified. Under enzyme-limiting conditions, the PAM end of the molecule is almost absolutely specified (specificity score $\geq +0.9$ for guide RNA-specified base pairs) by CLTA1, CLTA2, and CLTA3 guide RNAs (FIG. 2 and FIG. 6-9), and highly specified by CLTA4 guide RNA (specificity score of $+0.7$ to $+0.9$). Within this region of high specificity, specific single mutations, consistent with wobble pairing between the guide RNA and target DNA, that are tolerated. For example, under enzyme-limiting conditions for single-mutant sequences, a dA:dT off-target base pair and a guide RNA-specified dG:dC base pair are equally tolerated at position 17 out of 20 (relative to the non-PAM end of the target site) of the CLTA3 target site. At this position, an rG:dT wobble RNA:DNA base pair may be formed, with minimal apparent loss of cleavage activity.

Importantly, the selection results also reveal that the choice of guide RNA hairpin affects specificity. The shorter, less-active sgRNA v1.0 constructs are more specific than the longer, more-active sgRNA v2.1 constructs when assayed under identical, enzyme-saturating conditions that reflect an excess of enzyme relative to substrate in a cellular context (FIG. 2 and FIGS. 5-8). The higher specificity of sgRNA v1.0 over sgRNA v2.1 is greater for CLTA1 and CLTA2 (~ 40 -90% difference) than for CLTA3 and CLTA4 (< 40 % difference). Interestingly, this specificity difference is localized to different regions of the target site for each target sequence (FIGS. 2H and 26). Collectively, these results indicate that different guide RNA architectures result in different DNA cleavage specificities, and that guide RNA-dependent changes in specificity do not affect all positions in the target site equally. Given the inverse relationship between Cas9:sgRNA concentration and specificity described above, we speculate that the differences in specificity between guide RNA architectures arises from differences in their overall level of DNA-cleavage activities.

Effects of Cas9:sgRNA Concentration on DNA Cleavage Specificity. To assess the effect of enzyme concentration on patterns of specificity for the four target sites tested, we calculated the concentration-dependent difference in positional specificity and compared it to the maximal possible change in positional specificity (FIG. 25). In general, specificity was higher under enzyme-limiting conditions than enzyme-excess conditions. A change from enzyme-excess to enzyme-limiting conditions generally increased the specificity at the PAM end of the target by ≥ 80 % of the maximum possible change in specificity. Although a decrease in enzyme concentration generally induces small (~ 30 %) increases in specificity at the end of the target sites farthest from the PAM, concentration decreases induce much larger increases in specificity at the end of the target site nearest the PAM. For CLTA4, a decrease in enzyme concentration is accompanied by a small (~ 30 %) decrease in specificity at some base pairs near the end of the target site farthest from the PAM.

Specificity of PAM Nucleotides. To assess the contribution of the PAM to specificity, we calculated the abundance of all 16 possible PAM dinucleotides in the pre-selection and post-selection libraries, considering all observed post-selection target site sequences (FIG. 21) or considering only post-selection target site sequences that contained no mutations in the 20 base pairs specified by the guide RNA (FIG. 22). Considering all observed post-selection target site sequences, under enzyme-limiting conditions, GG dinucleotides represented 99.8%, 99.9%, 99.8%, and 98.5% of the post-selection PAM dinucleotides for selections with CLTA1, CLTA2,

CLTA3, and CLTA4 v2.1 sgRNAs, respectively. In contrast, under enzyme-excess conditions, GG dinucleotides represented 97.7%, 98.3%, 95.7%, and 87.0% of the post-selection PAM dinucleotides for selections with CLTA1, CLTA2, CLTA3, and CLTA4 v2.1 sgRNAs, respectively. These data demonstrate that an increase in enzyme concentration leads to increased cleavage of substrates containing non-canonical PAM dinucleotides.

To account for the pre-selection library distribution of PAM dinucleotides, we calculated specificity scores for the PAM dinucleotides (FIG. 23). When only on-target post-selection sequences are considered under enzyme-excess conditions (FIG. 24), non-canonical PAM dinucleotides with a single G rather than two Gs are relatively tolerated. Under enzyme-excess conditions, Cas9:CLTA4 sgRNA 2.1 exhibited the highest tolerance of non-canonical PAM dinucleotides of all the Cas9:sgRNA combinations tested. AG and GA dinucleotides were the most tolerated, followed by GT, TG, and CG PAM dinucleotides. In selections with Cas9:CLTA1, 2, or 3 sgRNA 2.1 under enzyme-excess conditions, AG was the predominate non-canonical PAM (FIGS. 23 and 24). Our results are consistent with another recent study of PAM specificity, which shows that Cas9:sgRNA can recognize AG PAM dinucleotides²³. In addition, our results show that under enzyme-limiting conditions, GG PAM dinucleotides are highly specified, and under enzyme-excess conditions, non-canonical PAM dinucleotides containing a single G can be tolerated, depending on the guide RNA context.

To confirm that the in vitro selection results accurately reflect the cleavage behavior of Cas9 in vitro, we performed discrete cleavage assays of six CLTA4 off-target substrates containing one to three mutations in the target site. We calculated enrichment values for all sequences in the post-selection libraries for the Cas9:CLTA4 v2.1 sgRNA under enzyme-saturating conditions by dividing the abundance of each sequence in the post-selection library by the calculated abundance in the pre-selection library. Under enzyme-saturating conditions, the single one, two, and three mutation sequences with the highest enrichment values (27.5, 43.9, and 95.9) were cleaved to $\geq 71\%$ completion (FIG. 27). A two-mutation sequence with an enrichment value of 1.0 was cleaved to 35%, and a two-mutation sequence with an enrichment value near zero (0.064) was not cleaved. The three-mutation sequence, which was cleaved to 77% by CLTA4 v2.1 sgRNA, was cleaved to a lower efficiency of 53% by CLTA4 v1.0 sgRNA (FIG. 28). These results indicate that the selection enrichment values of individual sequences are predictive of in vitro cleavage efficiencies.

To determine if results of the in vitro selection and in vitro cleavage assays pertain to Cas9:guide RNA activity in human cells, we identified 51 off-target sites (19 for CLTA1 and 32 for CLTA4) containing up to eight mutations that were both enriched in the in vitro selection and present in the human genome (Tables 3-5). We expressed Cas9:CLTA1 sgRNA v1.0, Cas9:CLTA1 sgRNA v2.1, Cas9:CLTA4 sgRNA v1.0, Cas9:CLTA4 sgRNA v2.1, or Cas9 without sgRNA in HEK293T cells by transient transfection and used genomic PCR and high-throughput DNA sequencing to look for evidence of Cas9:sgRNA modification at 46 of the 51 off-target sites as well as at the on-target loci; no specific amplified DNA was obtained for five of the 51 predicted off-target sites (three for CLTA1 and two for CLTA4).

Deep sequencing of genomic DNA isolated from HEK293T cells treated with Cas9:CLTA1 sgRNA or Cas9:CLTA4 sgRNA identified sequences evident of non-homologous end-joining (NHEJ) at the on-target sites and at five of the 49 tested off-target sites (CLTA1-1-1, CLTA1-2-2,

CLTA4-3-1, CLTA4-3-3, and CLTA4-4-8) (Tables 1 and 6-8). The CLTA4 target site was modified by Cas9:CLTA4 v2.1 sgRNA at a frequency of 76%, while off-target sites, CLTA4-3-1 CLTA4-3-3, and CLTA4-4-8, were modified at frequencies of 24%, 0.47% and 0.73%, respectively. The CLTA1 target site was modified by Cas9:CLTA1 v2.1 sgRNA at a frequency of 0.34%, while off-target sites, CLTA1-1-1 and CLTA1-2-2, were modified at frequencies of 0.09% and 0.16%, respectively.

Under enzyme-saturating conditions with the v2.1 sgRNA, the two verified CLTA1 off-target sites, CLTA1-1-1 and CLTA1-2-2, were two of the three most highly enriched sequences identified in the in vitro selection. CLTA4-3-1 and CLTA4-3-3 were the highest and third-highest enriched sequences of the seven CLTA4 three-mutation sequences enriched in the in vitro selection that are also present in the genome. The in vitro selection enrichment values of the four-mutation sequences were not calculated, since 12 out of the 14 CLTA4 sequences in the genome containing four mutations, including CLTA4-4-8, were observed at a level of only one sequence count in the post-selection library. Taken together, these results confirm that several of the off-target substrates identified in the in vitro selection that are present in the human genome are indeed cleaved by Cas9:sgRNA complexes in human cells, and also suggest that the most highly enriched genomic off-target sequences in the selection are modified in cells to the greatest extent.

The off-target sites we identified in cells were among the most-highly enriched in our in vitro selection and contain up to four mutations relative to the intended target sites. While it is possible that heterochromatin or covalent DNA modifications could diminish the ability of a Cas9:guide RNA complex to access genomic off-target sites in cells, the identification of five out of 49 tested cellular off-target sites in this study, rather than zero or many, strongly suggests that Cas9-mediated DNA cleavage is not limited to specific targeting of only a 7-12-base pair target sequence, as suggested in recent studies.^{11, 12, 19}

The cellular genome modification data are also consistent with the increase in specificity of sgRNA v1.0 compared to sgRNA v2.1 sgRNAs observed in the in vitro selection data and discrete assays. Although the CLTA1-2-2, CLTA 4-3-3, and CLTA 4-4-8 sites were modified by the Cas9-sgRNA v2.1 complexes, no evidence of modification at any of these three sites was detected in Cas9:sgRNA v1.0-treated cells. The CLTA4-3-1 site, which was modified at 32% of the frequency of on-target CLTA4 site modification in Cas9:v2.1 sgRNA-treated cells, was modified at only 0.5% of the on-target modification frequency in v1.0 sgRNA-treated cells, representing a 62-fold change in selectivity. Taken together, these results demonstrate that guide RNA architecture can have a significant influence on Cas9 specificity in cells. Our specificity profiling findings present an important caveat to recent and ongoing efforts to improve the overall DNA modification activity of Cas9:guide RNA complexes through guide RNA engineering.^{11, 15}

Overall, the off-target DNA cleavage profiling of Cas9 and subsequent analyses show that (i) Cas9:guide RNA recognition extends to 18-20 specified target site base pairs and a two-base pair PAM for the four target sites tested; (ii) increasing Cas9:guide RNA concentrations can decrease DNA-cleaving specificity in vitro; (iii) using more active sgRNA architectures can increase DNA-cleavage specificity both in vitro and in cells but impair DNA-cleavage specificity both in vitro and in cells; and (iv) as predicted by our in vitro results, Cas9:guide RNA can modify off-target sites in cells with up to four mutations relative to the on-target site. Our findings

provide key insights to our understanding of RNA-programmed Cas9 specificity, and reveal a previously unknown role for sgRNA architecture in DNA-cleavage specificity. The principles revealed in this study may also apply to Cas9-based effectors engineered to mediate functions beyond DNA cleavage.

Equivalents and Scope

Those skilled in the art will recognize, or be able to ascertain using no more than routine experimentation, many equivalents to the specific embodiments of the invention described herein. The scope of the present invention is not intended to be limited to the above description, but rather is as set forth in the appended claims.

In the claims articles such as “a,” “an,” and “the” may mean one or more than one unless indicated to the contrary or otherwise evident from the context. Claims or descriptions that include “or” between one or more members of a group are considered satisfied if one, more than one, or all of the group members are present in, employed in, or otherwise relevant to a given product or process unless indicated to the contrary or otherwise evident from the context. The invention includes embodiments in which exactly one member of the group is present in, employed in, or otherwise relevant to a given product or process. The invention also includes embodiments in which more than one, or all of the group members are present in, employed in, or otherwise relevant to a given product or process.

Furthermore, it is to be understood that the invention encompasses all variations, combinations, and permutations in which one or more limitations, elements, clauses, descriptive terms, etc., from one or more of the claims or from relevant portions of the description is introduced into another claim. For example, any claim that is dependent on another claim can be modified to include one or more limitations found in any other claim that is dependent on the same base claim. Furthermore, where the claims recite a composition, it is to be understood that methods of using the composition for any of the purposes disclosed herein are included, and methods of making the composition according to any of the methods of making disclosed herein or other methods known in the art are included, unless otherwise indicated or unless it would be evident to one of ordinary skill in the art that a contradiction or inconsistency would arise.

Where elements are presented as lists, e.g., in Markush group format, it is to be understood that each subgroup of the elements is also disclosed, and any element(s) can be removed from the group. It is also noted that the term “comprising” is intended to be open and permits the inclusion of additional elements or steps. It should be understood that, in general, where the invention, or aspects of the invention, is/are referred to as comprising particular elements, features, steps, etc., certain embodiments of the invention or aspects of the invention consist, or consist essentially of, such elements, features, steps, etc. For purposes of simplicity those embodiments have not been specifically set forth in *haec verba* herein. Thus for each embodiment of the invention that comprises one or more elements, features, steps, etc., the invention also provides embodiments that consist or consist essentially of those elements, features, steps, etc.

Where ranges are given, endpoints are included. Furthermore, it is to be understood that unless otherwise indicated or otherwise evident from the context and/or the understanding of one of ordinary skill in the art, values that are expressed as ranges can assume any specific value within the stated ranges in different embodiments of the invention, to the tenth of the

unit of the lower limit of the range, unless the context clearly dictates otherwise. It is also to be understood that unless otherwise indicated or otherwise evident from the context and/or the understanding of one of ordinary skill in the art, values expressed as ranges can assume any subrange within the given range, wherein the endpoints of the subrange are expressed to the same degree of accuracy as the tenth of the unit of the lower limit of the range.

In addition, it is to be understood that any particular embodiment of the present invention may be explicitly excluded from any one or more of the claims. Where ranges are given, any value within the range may explicitly be excluded from any one or more of the claims. Any embodiment, element, feature, application, or aspect of the compositions and/or methods of the invention, can be excluded from any one or more claims. For purposes of brevity, all of the embodiments in which one or more elements, features, purposes, or aspects is excluded are not set forth explicitly herein.

Tables

Table 1. Cellular modification induced by Cas9:CLTA4 sgRNA.

33 human genomic DNA sequences were identified that were enriched in the Cas9:CLTA4 v2.1 sgRNA in vitro selections under enzyme-limiting or enzyme-saturating conditions. Sites shown with underline contain insertions or deletions (indels) that are consistent with significant Cas9: sgRNA-mediated modification in HEK293T cells. In vitro enrichment values for selections with Cas9:CLTA4 v1.0 sgRNA or Cas9:CLTA4 v2.1 sgRNA are shown for sequences with three or fewer mutations. Enrichment values were not calculated for sequences with four or more mutations due to low numbers of in vitro selection sequence counts. Modification frequencies (number of sequences with indels divided by total number of sequences) in HEK293T cells treated with Cas9 without sgRNA (“no sgRNA”), Cas9 with CLTA4 v1.0 sgRNA, or Cas9 with CLTA4 v2.1 sgRNA. P-values are listed for those sites that show significant modification in v1.0 sgRNA- or v2.1 sgRNA-treated cells compared to cells treated with Cas9 without sgRNA. “Not tested (n.t.)” indicates that PCR of the genomic sequence failed to provide specific amplification products.

Table 2: Raw selection sequence counts. Positions -4 to -1 are the four nucleotides preceding the 20-base pair target site. PAM1, PAM2, and PAM3 are the PAM positions immediately following the target site. Positions +4 to +7 are the four nucleotides immediately following the PAM.

Table 3: CLTA1 genomic off-target sequences. 20 human genomic DNA sequences were identified that were enriched in the Cas9:CLTA1 v2.1 sgRNA in vitro selections under enzyme-limiting or enzyme-excess conditions. “m” refers to number of mutations from on-target sequence with mutations shown in lower case. Sites shown with underline contain insertions or deletions (indels) that are consistent with significant Cas9:sgRNA-mediated modification in HEK293T cells. Human genome coordinates are shown for each site (assembly GRCh37). CLTA1-0-1 is present at two loci, and sequence counts were pooled from both loci. Sequence counts are shown for amplified and sequenced DNA for each site from HEK293T cells treated with Cas9 without sgRNA (“no sgRNA”), Cas9 with CLTA1 v1.0 sgRNA, or Cas9 with CLTA1 v2.1 sgRNA.

Table 4: CLTA4 genomic off-target sequences. 33 human genomic DNA sequences were identified that were enriched in the Cas9:CLTA4 v2.1 sgRNA in vitro selections under

enzyme-limiting or enzyme-excess conditions. “m” refers to number of mutations from on-target sequence with mutations shown in lower case. Sites shown with underline contain insertions or deletions (indels) that are consistent with significant Cas9:sgRNA-mediated modification in HEK293T cells. Human genome coordinates are shown for each site (assembly GRCh37). Sequence counts are shown for amplified and sequenced DNA for each site from HEK293T cells treated with Cas9 without sgRNA (“no sgRNA”), Cas9 with

CLTA4 v1.0 sgRNA, or Cas9 with CLTA4 v2.1 sgRNA. Table 5: genomic coordinates of CLTA1 and CLTA4 off-target sites. 54 human genomic DNA sequences were identified that were enriched in the Cas9:CLTA1 v2.1 sgRNA in vitro selections under enzyme-limiting or enzyme-excess conditions. Human genome coordinates are shown for each site (assembly GRCh37).

Table 6: Cellular modification induced by Cas9:CLTA1 sgRNA. 20 human genomic DNA sequences were identified that were enriched in the Cas9:CLTA1 v2.1 sgRNA in vitro selections under enzyme-limiting or enzyme-excess conditions. Sites shown with underline contain insertions or deletions (indels) that are consistent with significant Cas9:sgRNA-mediated modification in HEK293T cells. In vitro enrichment values for selections with Cas9:CLTA1 v1.0 sgRNA or Cas9:CLTA1 v2.1 sgRNA are shown for sequences with three or fewer mutations. Enrichment values were not calculated for sequences with four or more mutations due to low numbers of in vitro selection sequence counts. Modification frequencies (number of sequences with indels divided by total number of sequences) in HEK293T cells treated with Cas9 without sgRNA (“no sgRNA”), Cas9 with CLTA1 v1.0 sgRNA, or Cas9 with CLTA1 v2.1 sgRNA. P-values of sites that show significant modification in v1.0 sgRNA- or v2.1 sgRNA-treated cells compared to cells treated with Cas9 without sgRNA were 1.1E-05 (v1.0) and 6.9E-55 (v2.1) for CLTA1-0-1, 2.6E-03 (v1.0) and 2.0E-10 (v2.1) for CLTA1-1-1, and 4.6E-08 (v2.1) for CLTA1-2-2. P-values were calculated using a one-sided Fisher exact test. “Not tested (n.t.)”

indicates that the site was not tested or PCR of the genomic sequence failed to provide specific amplification products.

Table 7: CLTA1 genomic off-target indel sequences. Insertion and deletion-containing sequences from cells treated with amplified and sequenced DNA for the on-target genomic sequence (CLTA1-0-1) and each modified off-target site from HEK293T cells treated with Cas9 without sgRNA (“no sgRNA”), Cas9 with CLTA1 v1.0 sgRNA, or Cas9 with CLTA1 v2.1 sgRNA. “ref” refers to the human genome reference sequence for each site, and the modified sites are listed below. Mutations relative to the on-target genomic sequence are shown in lowercase letters. Insertions and deletions are shown in underlined bold letters or dashes, respectively. Modification percentages are shown for those conditions (v1.0 sgRNA or v2.1 sgRNA) that show statistically significant enrichment of modified sequences compared to the control (no sgRNA).

Table 8: CLTA4 genomic off-target indel sequences. Insertion and deletion-containing sequences from cells treated with amplified and sequenced DNA for the on-target genomic sequence (CLTA4-0-1) and each modified off-target site from HEK293T cells treated with Cas9 without sgRNA (“no sgRNA”), Cas9 with CLTA4 v1.0 sgRNA, or Cas9 with CLTA4 v2.1 sgRNA. “ref” refers to the human genome reference sequence for each site, and the modified sites are listed below. Mutations relative to the on-target genomic sequence are shown in lowercase letters. Insertions and deletions are shown in underlined bold letters or dashes, respectively. Modification percentages are shown for those conditions (v1.0 sgRNA or v2.1 sgRNA) that show statistically significant enrichment of modified sequences compared to the control (no sgRNA).

Table 9: Oligonucleotides used in this study. All oligonucleotides were purchased from Integrated DNA Technologies. An asterisk (*) indicates that the preceding nucleotide was incorporated as a hand mix of phosphoramidites consisting of 79 mol % of the phosphoramidite corresponding to the preceding nucleotide and 4 mol % of each of the other three canonical phosphoramidites. “/SPhos/” denotes a 5' phosphate group installed during synthesis.

TABLE 1

| | # of | Mutations sequence | SEQ ID NO. | gene | in vitro enrichment | |

What is claimed is:

1. A method for identifying a target site of an RNA-programmable nuclease, the method comprising

- (a) providing an RNA-programmable nuclease that cuts a double-stranded nucleic acid target site, wherein cutting of the target site results in cut nucleic acid strands comprising a 5' phosphate moiety;
- (b) contacting the RNA-programmable nuclease of (a) with a library of candidate nucleic acid molecules, wherein each nucleic acid molecule comprises a concatenamer of a sequence comprising a candidate nuclease target site and a constant insert sequence of at least 10 and not more than 70 nucleotides, under conditions suitable for the RNA-programmable nuclease to cut a candidate nucleic acid molecule comprising a target site of the RNA-programmable nuclease; and
- (c) identifying nuclease target sites cut by the RNA-programmable nuclease in (b) by direct sequencing of an intact nuclease target site on the nucleic acid strand that was cut by the RNA-programmable nuclease in step (b), wherein the method does not include computational reconstruction of nuclease target sites from cut half-sites.

2. The method of claim 1, wherein the method identifies off-target sites of the RNA-programmable nuclease.

3. The method of claim 1, wherein the RNA-programmable nuclease creates blunt ends.

4. The method of claim 1, wherein of step (c) comprises ligating a first nucleic acid adapter to the 5' end of a nucleic acid strand that was cut by the RNA-programmable nuclease in step (b) via 5'-phosphate-dependent ligation.

5. The method of claim 4, wherein the nucleic acid adapter is provided in double-stranded form.

6. The method of claim 5, wherein the 5'-phosphate-dependent ligation is a blunt end ligation.

7. The method of claim 4, wherein step (c) comprises amplifying a fragment of the concatenamer cut by the RNA-programmable nuclease that comprises an uncut target site via a PCR reaction using a PCR primer that hybridizes with the adapter and a PCR primer that hybridizes with the constant insert sequence.

8. The method of claim 7, wherein the method further comprises enriching the amplified nucleic acid molecules for molecules comprising a single uncut target sequence.

9. The method of claim 1, wherein step (c) comprises sequencing the nucleic acid strand that was cut by the nuclease in step (b), or a copy thereof obtained via PCR, using a high-throughput sequencing method.

10. The method of claim 1, wherein the library of candidate nucleic acid molecules comprises at least 10^{10} , different candidate nuclease cleavage sites.

11. The method of claim 1, wherein the nuclease is a therapeutic nuclease which cuts a specific nuclease target site in a gene associated with a disease.

65

239

12. The method of claim 11, further comprising determining a maximum concentration of the therapeutic nuclease at which the therapeutic nuclease cuts the specific nuclease target site, and does not an additional nuclease target site.

13. The method of claim 12, further comprising administering the therapeutic nuclease to a subject in an amount effective to generate a final concentration equal or lower than the maximum concentration.

14. The method of claim 1, wherein the nuclease is an RNA-programmable nuclease that forms a complex with an RNA molecule, and wherein the nuclease:RNA complex specifically binds a nucleic acid sequence complementary to the sequence of the RNA molecule.

15. The method of claim 14, wherein the RNA molecule is a single-guide RNA (sgRNA).

16. The method of claim 14, wherein the RNA molecule comprises 15-25 nucleotides that are complementary to the target sequence.

17. The method of claim 1, wherein the nuclease is a Cas9 nuclease.

18. The method of claim 14, wherein the nuclease target site comprises a [sgRNA-complementary sequence]-

240

[protospacer adjacent motif (PAM)] structure, and the nuclease cuts the target site within the sgRNA-complementary sequence.

19. The method of claim 18, wherein the sgRNA-complementary sequence comprises 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, or 30 nucleotides.

20. The method of claim 1, wherein step (c) comprises identifying nuclease target sites cut by the RNA-programmable nuclease by direct, single-end sequencing of an intact nuclease target site on the nucleic acid strand that was cut by the RNA-programmable nuclease.

21. The method of claim 1, wherein both a cut half-site and an adjacent uncut nuclease target site of the same library member are contained within a 100 nucleotide sequence.

22. The method of claim 1, wherein the constant insert sequence comprises not more than 60 nucleotides.

23. The method of claim 1, wherein the constant insert sequence comprises not more than 55 nucleotides.

24. The method of claim 1, wherein the library of candidate nucleic acid molecules comprises at least 10^{12} different candidate nuclease cleavage sites.

UNITED STATES PATENT AND TRADEMARK OFFICE
CERTIFICATE OF CORRECTION

PATENT NO. : 9,163,284 B2
APPLICATION NO. : 14/320370
DATED : October 20, 2015
INVENTOR(S) : Liu et al.

Page 1 of 1

It is certified that error appears in the above-identified patent and that said Letters Patent is hereby corrected as shown below:

In the Claims

Claim 4, column 238, line 41:

“wherein of step (c)” should be changed to --wherein step (c)--.

Claim 10, column 238, line 63:

“at least 10^{10} , different” should be changed to --at least 10^{10} different--.

Signed and Sealed this
Fourteenth Day of June, 2016
